Undesirable side effects of morphine and meperidine were less noticeable when atropine or scopolamine was added. Subjects were more sedated when scopolamine was injected with each analgesic.

Neostigmine increased both intensity and duration of the analgesic action of morphine, meperidine and methadon as measured by determination of pain thresholds.

Premedication agents should be selected for sedative effects rather than for their analgesic actions. Methadon is most useful as an analgesic in postoperative subjects and in cases of pain from many other causes.

Pain threshold studies of 11 subjects were made by the Wolff, Hardy, Goodell technic. Eighty clinical cases are reported.

ABSTRACT OF DISCUSSION

Dr. Leo V. Hand, Boston: Dr. Christensen's laboratory findings substantiate those of other investigators as to comparative effects on threshold and duration with morphine, meperidine and methadon. Methadon has three times the potency of morphine and approximately thirty times the potency of meperidine. Like meperidine, there is an absence of nausea and vomiting. As to side effects, there seems to be a difference of opinion. Dr. Christensen reports only a slight sedative effect when the drug is administered subcutaneously and no other undesirable side actions. Other investigators report a 50 per cent incidence of lightheadedness or dizziness, but not true vertigo. Also, they report that when large doses are used there is not only respiratory depression but also circulatory changes: fall in blood pressure levels and, in particular, changes in rate and pronounced bradycardia. Forty patients of the 69 had nitrous oxide anesthesia. The majority of these 40 patients had abdominal surgical treatment. These patients who were to have abdominal surgical treatment under nitrous oxide required heavy doses of "pentothal" for intubation and curare for relaxation. If one were to eliminate this group in which nitrous oxide plus "pentothal" was given, one would eliminate approximately 50 to 57 per cent of the patients from evaluation of preanesthetic medication studies, as well as an appreciable period of postoperative medication studies. An opiate or its counterpart should not be used for strictly sedative purposes; the barbituric acid derivatives are more effective. I do not believe that premedication influences an anesthetic course or relaxation of the patient. It is the important factor in a smooth induction. Relaxation is dependent entirely on the administrator and type and quantity of agent administered. How many of these surgical procedures in these 69 patients might be classified as major procedures usually accompanied by two or more days of moderate to severe postoperative pain? Our results on the efficacy of morphine plus neostigmine do not approach those of Dr. Christensen with methadon. She reports that 44 of 61 patients experienced no pain the first postoperative day. In our statistics on 400 patients, we found that patients who received morphine plus neostigmine required an average total dose of 30 mg. of morphine for the first twenty-four hours and 20 mg. of morphine for the second twenty-four hour period. Of the patients receiving morphine alone, the average total dose was 50 mg. the first twenty-four hours and 30 mg. the second twenty-four hours.

Dr. Benjamin H. Robbins, Nashville, Tenn.: From data presented in charts 1, 3, 4 and 5, the degree of analgesia produced by 5, 15 and 150 mg. of methadon, morphine and meperidine, respectively, is about the same. These data place methadon as about three times as active as morphine, which is greater than other reports (Kirchhof, A. C., and David, N. A.: Clinical Trial of a New Synthetic Heptonone Analgesic [Dolophine]: Preliminary Report, West. J. Surg. 55: 183-186 [March] 1947) and our own observations indicate. Our experience with methadon has shown that it may be substituted for morphine or meperidine in a great variety of uses. For preanesthetic medication doses of 7.5 mg. combined with atropine, gave good effects. A smaller dose is not as satisfactory as 10 mg. of morphine. For postoperative pain, a dose of 5 or 7.5 mg. every six hours has been satisfactory in all cases except 2. It has given good relief after gastrectomy, sympathectomy, lobectomy, pneumonectomy, thoracoplasty and less extensive procedures. It controls pain in coronary occlusion and acute rheumatic pericarditis, but the dose has to be increased and repeated more frequently. Three patients who showed sensitivity reactions to opiates, tolerated methadon well. Three patients addicted to morphine, taking 0.250 to 0.6 Gm. daily, were changed to methadon, 7.5 to 10 mg. every four to six hours, without discomfort, and in 2 of these the methadon was gradually withdrawn in five to six days without the development of abstinence signs or symptoms. One meperidine addict, using 30 to 40 cc. per day, 1.5 to 2.25 Gm., was changed to methadon, 20 mg. six times daily for three days, and now is down to two doses daily without signs of meperidine abstinence. These experiences agree with those reported by Isbell and others (Isbell, H.; Walker, A.; Eisenman, A. J., and Frank, K.: Effect of Single Doses of 10820 [4-4 Diphenyl—6-Dimethylamine-Heptonone-3] on Man, Federation Proc. 6: 341 [March] 1947). Reports from the First United States Narcotic Farm indicate that regular and repeated use of methadon may lead to addiction. Psychic effects of methadon are less than with morphine and evidence of physical dependence is less, so it is possible that this substance may not be a true addictive drug. If experience shows that methadon, unlike morphine or meperidine, is free of addiction liabilities, this new substance will be the greatest addition to that list of pain-relieving drugs since the introduction of morphine or its precursor, opium.

Dr. John S. Lundy, Rochester, Minn.: My associates and I have 1 patient who has some euphoria from methadon. He is a physician who has suddenly contracted rheumatoid arthritis and has acute attacks. He gets complete relief with this substance but he gets euphoria from it. He gets no thrill from meperidine or morphine. We have had unfortunate experiences with meperidine. It can be the worst addictive drug that we have used. It is only in rare instances that it is so addictive, but for those persons to whom it gives euphoria it does something for which they would never give it up for anything in this world. We have had several patients now who have come in addicted to morphine and we have started them on methadon. For the first two or three days they say it gives relief from the pain but does not give them any thrill So far, however, we have had no trouble taking patients off morphine and using methadon. In order to be sure that this is a pain-relieving drug, we have tried it now in a number of cases in which spinal anesthesia has worn off before a hernia operation was completed and we have been able to get fifteen minutes of relief from pain for each 10 mg. given intravenously, for even as many as three doses in order that an operation might be completed. I think that is a definite test for pain relief. There are many things about this drug that are interesting. We gave one man, after a Smithwick operation when he suffered tremendous amount of pain, 28 mg. every four hours for six days, and he finally experienced an over-dose. He looked extremely ill, and the question of damage to the liver came up. All of the tests for damage to the liver that are done in our institution were applied and appeared to be normal as far as liver function was concerned. Our series is not large—I think perhaps 175 cases—but we feel that this drug has potential virtue.

Dr. Eunice Christensen, Iowa City, Iowa: The subjects who took 2.5 and 5.0 mg. doses of methadon in the laboratory for investigative purposes experienced some dizziness and lightheadedness occasionally after subcutaneous injection, and more frequently for a few minutes after the doses were given intravenously. Respiration rates and blood pressure were checked before and every fifteen to twenty minutes after administration of 1.25 to 5.0 mg. doses of methadon for the duration of analgesia. No significant changes were noted. The majority of the patients who had nitrous oxide anesthesia had bowel or gastric resections, laminectomies, operations on the chest, etc.—procedures after which pain might be expected. The patients in the nitrous oxide group who were premedicated with methadon probably needed more "pentothal" than those who received morphine preoperatively because methadon lacked sedative properties. Our series of clinical cases is small. Possibly after we have given methadon to a larger group, we, too, may feel that greater doses are needed in certain cases relieved only partially by 2.5 or 5.0 mg. of methadon. Dr. Robbins asked the reason for the increased pain threshold and duration effect when neostigmine was given with the analgesic agent. We believe this was a summation effect. We do not know why atropine and scopolamine shortened the analgesic effect of the three drugs. That problem is now being studied. Our clinical patient who noted euphoria after methadon did not experience it from morphine or meperidine. One of the laboratory subjects for the pain threshold tests had pronounced euphoria after both meperidine and morphine injections. He disliked methadon because it didn't give him a "kick."

Ascites.—There are three important physiopathologic states which lead to the formation of ascites. The first and most frequently observed one is cirrhosis of the liver. The second cause is the implantation of a malignant neoplasm of the peritoneum usually secondary to carcinoma of the gastrointestinal tract or the ovary, but occasionally the neoplasm is primary such as a mesothelioma. Thirdly, cirrhosis of the liver due to repeated and long-standing congestive heart failure may lead to ascites.—Lord, J. W., Jr., from an address given April 29 at the Clinical Research Meeting of the New York Academy of Medicine, New York.

FATAL TOXIC ENCEPHALOPATHY APPARENTLY CAUSED BY STREPTOMYCIN

THOMAS HUNNICUTT, M.D.
WILLIAM J. GRAF, M.D.
MORTON HAMBURGER, M.D.
EUGENE B. FERRIS, M.D.
and
I. MARK SCHEINKER, M.D.
Cincinnati

Few fatal complications of streptomycin therapy have been reported in the medical literature.[1] However, it is well recognized that streptomycin produces dysfunction of the eighth cranial nerve in man [2] and that its administration is sometimes followed by symptoms which are best explained by the assumption that temporary damage to nervous or vascular tissue has occurred. Thus, paresthesias of the hands, the tongue and the circumoral region are not uncommon.[3] Furthermore, there is on record at least one report of convulsions having occurred during the administration of streptomycin intravenously.[4] We have recently witnessed a case of fatal encephalopathy which we believe was caused by streptomycin. The observations may throw some light on the nature of the nervous manifestations of streptomycin intoxication and on the relation of renal function to blood levels of the drug.

REPORT OF CASE

The patient was a white married woman aged 25. She had had diabetes since the age of 6, but had controlled it adequately by the use of diet and insulin.

Her present illness began in April 1946, when albuminuria and pyuria were detected by an obstetrician, in the second month of pregnancy. The pregnancy was terminated and the fallopian tubes ligated in June 1946, after the pyelonephritis had persisted and poor renal function had been demonstrated. Postoperatively a wound infection appeared and drained for several weeks. During this time she suffered from intermittent lumbar pain and fever, which recurred after her discharge from the hospital, necessitating her readmission. A third admission, for ten days, was required for another exacerbation of the infection of the urinary tract. Penicillin and sulfonamide compound were administered during each of these hospitalizations.

During the two month interval between her third and fourth (last) admissions, she suffered from frequent lumbar pain and from crops of small furuncles. She lost 28 pounds (12.7 Kg.) in weight.

On her final admission,[5] Oct. 4, 1946, physical examination showed a well developed but thin and pale young woman, not in acute distress. The temperature was 99.4 F., the pulse rate 120, the respirations 24 and the blood pressure 140 systolic and 90 diastolic. An acneiform pustular eruption was noted over the face and upper anterior part of the chest. The ocular fundi were normal, and abnormalities were not noted in the heart and lungs. Tenderness was noted in both costovertebral angles and in both lower quadrants of the abdomen, but no masses or organs were palpated. Pelvic examination was not done.

The laboratory findings on admission were as follows: The red blood cell count was 3,300,000; hemoglobin, 8.7 Gm.; white blood cell count, 19,000; differential count: stab forms 7 per cent, polymorphonuclear leukocytes 82 per cent, lymphocytes 10 per cent and monocytes 1 per cent. Urine: The specific gravity was 1.015; albumin, 4 plus; sugar, 4 plus; acetone, absent; microscopic examination: there were many white blood

[5] The three previous admissions were to hospitals other than that of the final admission.

cells in clumps and red blood cells, but no casts. Blood sugar was 580 mg. per hundred cubic centimeters, the carbon dioxide-combining power 48 volumes per cent and the urea nitrogen 47 mg. per hundred cubic centimeters. A hemolytic Staphylococcus aureus was isolated from the urine and from a pustule on the forehead.

Course in Hospital.—The initial period in the hospital was characterized by fever, pyuria and costovertebral pain. The patient presented several problems in management, in addition to the active pyelonephritis. The diabetes was difficult to stabilize because of variations in food and fluid intake related to situations of emotional stress. By means of a diet high in carbohydrates and parenteral supplementation of fluids and dextrose, together with 10 to 40 units of regular insulin and 20 to 40 units of protamine zinc insulin a day, the diabetes was fairly well controlled. At no time did ketosis develop. The blood urea nitrogen level, which was initially 47 mg. per hundred cubic centimeters, slowly fell to normal after nine days of forced fluids, the delayed fall indicating a pronounced restriction of renal function.

The patient received 240,000 units of penicillin daily for the first four days and then 600,000 units daily for the next six days. At this time she was afebrile, but manifestations of active pyelonephritis continued and the urine culture remained positive for staphylococci. The furuncles did not heal. Because of the persistence of white blood cells and staphylococci in the urine, the sensitivity of the micro-organisms to penicillin and streptomycin was tested. Serial dilution technics were employed, the streptomycin tests in tryptone broth, and the penicillin tests in yeast beef broth. The results are shown in table 1.

Table 1.—*Sensitivity of Staphylococci to Penicillin and Streptomycin*

	Penicillin, Oxford Units/Cc. Required to Inhibit Growth	Streptomycin, Micrograms/Cc. Required to Inhibit Growth
Staphylococcus from boil..........	0.4	1.5
Staphylococcus from urine.........	>25	1.5

Because of the resistance of the organism in the urine to penicillin and its sensitivity to streptomycin, penicillin was discontinued and streptomycin was started in doses of 400 mg. every three hours, on the eleventh hospital day. Within two days the pus had disappeared from the urine and the urine culture was negative. At this time the patient presented no complaints or problems, and was able to be up and about. A new batch of streptomycin was started on the third day of treatment. That day she complained of headache. On the fourth day of treatment, she noticed paresthesias of the face (circumoral), tongue and fingers.

On the fifth day, while talking to her husband, she suddenly became disoriented and began to exhibit athetoid and choreiform movements of the head and all extremities. Streptomycin was discontinued; the total dose had been 15.6 Gm. in five days. The temperature, pulse, respirations and blood pressure at that time were normal. The blood urea nitrogen was 21 mg. per hundred cubic centimeters, the blood sugar 320 mg. per hundred cubic centimeters, the carbon dioxide-combining power 50 volumes per cent and the cerebrospinal fluid normal as to pressure, cytology and protein content. The temperature rose rapidly to 106 F.; the pulse rate reached 128. The respirations gradually became faster, being 40 per minute until Cheyne-Stokes breathing began. The blood pressure, which was normal at the onset of the toxic reaction, rose to 195 systolic and 125 diastolic several hours before death. The patient lapsed into a coma, suffered numerous generalized convulsions, and died at 6:25 p. m., Oct. 21, 1946.

The level of streptomycin in the serum and urine was determined at frequent intervals, and that of cerebrospinal fluid once, by a modification of the method of Price, Nielsen and Welch.[6] The results are presented in table 2.

Table 2.—*Levels of Streptomycin in Serum, Urine and Spinal Fluid, Micrograms per Cubic Centimeter*

October 21..........................	25	...	..

The clinical diagnoses were juvenile diabetes mellitus, diabetic vascular disease, acute and chronic pyelonephritis, abscesses (Staphylococcus) of kidneys and skin, and terminal toxic encephalopathy due to streptomycin.

An autopsy was performed five hours post mortem by Dr. Edward A. Gall.[7] The significant findings were confined to the peritoneal cavity, the pancreas, the kidneys and the brain, which are described in the following paragraphs. All other organs were normal.

Peritoneal Cavity.—There was no free fluid. The omentum and loops of the ileum were bound in the lower part of the abdomen to the right posterolateral surface of the uterus and to the under surface of the abdominal scar. Blunt dissection in this region revealed a multiloculated abscess cavity proceeding from the right adnexa and containing approximately 30 cc. of creamy, yellowish odorless pus. Culture of this showed hemolytic Staph. aureus. This cavity was well walled off, and the posterior surface of the bladder was adherent to it by fibrinous strands.

Pancreas.—Gross Examination: This organ was decidedly atrophied, comprising only about one-fourth its normal bulk. There was considerable fibrosis, but lobulation was retained. The parenchymatous components were markedly attenuated.

Microscopic Examination: Despite the gross impression of atrophy, abundant parenchyma persisted. There were, however, only rare islets, and these showed much attenuation.

Kidneys—Gross Examination: The kidneys weighed together 220 Gm., and were roughly symmetric. There was moderate edema of the perirenal fat which adhered unduly to the true capsule. The latter stripped with ease and revealed an irregular mottled yellowish red surface. On section there were several cortical cystic abscesses measuring up to 0.8 cm., containing yellowish gray purulent fluid. The cortex was narrowed to 3 mm., and there were many minute bright yellow foci of necrosis with streaklike appearance. These were distributed predominantly among the pyramids, and several of the latter showed frank dissociation. The pelves were not dilated, nor was the mucosa significantly injected.

Microscopic Examination: All sections showed a severe degree of pyelonephritis of chronic character with focal tubular atrophy, interstitial inflammation and glomerular hyalinization. Many large vessels exhibited considerable arteriosclerosis. Where not atrophied the majority of the proximal tubules showed swollen, vacuolated and granular cytoplasm. The lumens were obtruded on and the picture was that of hydropic swelling. Glomeruli exhibited considerable intercapillary sclerosis, and a few contained "hyalin ball-like deposits." A peculiar autolytic necrosis of several pyramids was noted, and in these there appeared to be some calcification. The pelvic mucosa elsewhere showed chronic inflammation and edema.

Brain—Gross Examination: The brain, except for a slight flattening of the gyri, was grossly normal. The vessels at the base were thin walled and normally distributed. Coronal sections through both hemispheres revealed a moderate degree of swelling of the white matter and a diffuse congestion, especially pronounced throughout the cortical gray substance (fig. 1).

Microscopic Examination: Survey sections were taken from various regions of the gray and white matter of both hemispheres, from the hypothalamus and the medulla. The microscopic examination disclosed two principal types of changes: (1) vascular alterations and (2) lesions of the nervous tissue proper.

[7] Pathologist, Bethesda Hospital.

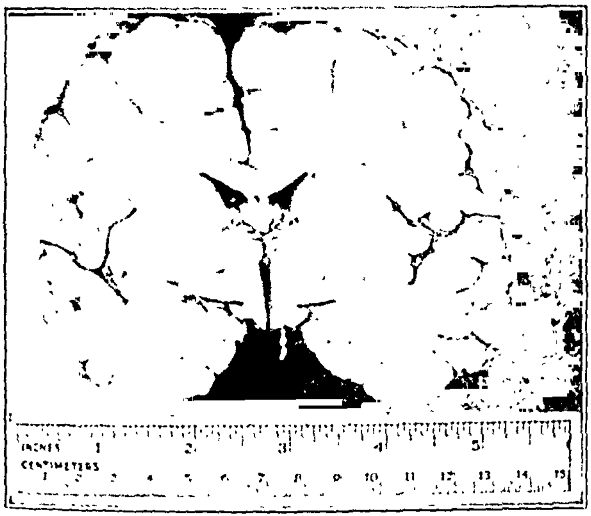

Fig. 1.—Coronal section through both hemispheres at the level of the optic chiasm. Note the enlargement of the white matter of both hemispheres associated with compression of the lateral ventricles.

The vascular changes were of uniform character, varying only in degree, and were confined chiefly to the cerebral white matter, basal ganglions and medulla. The changes consisted of a tremendous distention of the smaller veins and capillaries and of signs of stasis and vasoparalysis (fig. 2). Some of the perivascular spaces appeared distended and harbored serous fluid, extravasated red blood cells and macrophages. Some of the veins showed signs of beginning vessel wall necrosis.

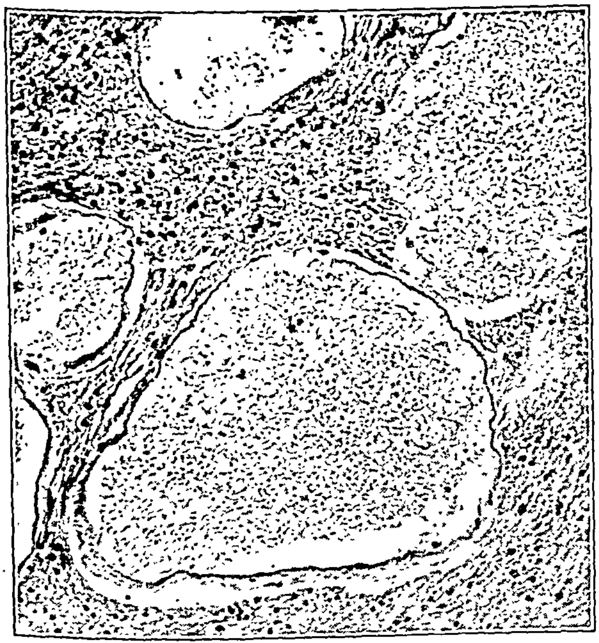

Fig. 2.—Vascular alterations of the medulla. Note the tremendous distention of the capillaries. Hematoxylin eosin stain; × 260.

The lesions of the nervous tissue proper consisted of small focal areas of rarefaction and necrosis; early stage of swelling of the white matter; ischemic degeneration of some of the nerve cells, especially pronounced in the areas adjacent to the distended blood vessels. The cytoplasm of some of the nerve cells contained brownish hematogenous pigment.

Sections taken from the hypothalamus disclosed a few petechial hemorrhages involving the nucleus paraventricularis and the nucleus supraopticus. The neuronal elements, however, appeared only slightly damaged.

In sections taken from the medulla there were numerous distended capillaries and veins with changes characteristic of vasoparalysis. In addition, there were a few focal areas of tissue rarefaction in which some of the nerve cells displayed signs of a far advanced ischemic degeneration.

The cranial nerves, including the eighth nerve, did not reveal any pathologic abnormalities.

The leptomeninges were moderately distended and harbored a few red blood cells and macrophages.

The final neuropathologic diagnoses were: functional vascular disturbances of the white matter; medulla and basal ganglions characteristic of vasoparalysis, associated with secondary cerebral swelling and ischemic alterations of the nerve cells of the nuclei and of the cortical gray matter; petechial hemorrhages in the paraventricular and supraoptic nuclei of the hypothalamus.

Summary on the Lesions of the Central Nervous System and General Comment.—The most striking changes consisted of vascular alterations described as central vasoparalysis.[8] Vascular changes of the same type have been observed repeatedly in cases of brain injury[9] in arsphenamine encephalopathy[10] and other toxic encephalopathies.

There is little doubt that the described alterations of the nervous tissue are secondary to the vascular changes. Whereas in the other examples of central vasoparalysis[11] the circulatory disturbances were chiefly confined to the white matter, in the present case the vascular changes were also found in the hypothalamus, basal ganglions and the medulla. It is conceivable that the involvement of the medulla contributed to the rapid fatal outcome of the present case.

The final pathologic diagnoses were: (1) functional vascular disturbances of the white matter, medulla (early stage of vasoparalysis) and basal ganglious with secondary cerebral swelling and ischemic alterations of the nerve cells of the nuclei and of the cortical gray matter; petechial hemorrhages in the paraventricular and supraoptic nuclei of the hypothalamus; (2) pyelonephritis, acute and chronic with formation of miliary abscesses and acute necrotizing papillitis; (3) intercapillary glomerulosclerosis; (4) nephritis, chronic vascular, severe; (5) toxic nephrosis, with hydropic degeneration of renal tubules, and (6) acute suppurative salpingo-oophoritis with abscess formation on the right side.

COMMENT

It seemed probable that the events leading to the death of this young woman represented an encephalopathy caused by streptomycin, the symptoms of which appeared with dramatic suddenness on the fifth day of treatment. Three days later the patient was dead. The clinical picture was not that of uremia, diabetic ketosis or insulin shock, and the laboratory studies did not reveal changes characteristic of these conditions. Furthermore, the patient's course up to the time of development of the encephalopathy had been one of improvement, both of the staphylococcic infection of the kidneys and skin and in the stability of the diabetes. The cutaneous lesions were healing, the temperature had subsided, the urine culture had become negative, and the pyuria had diminished. In the face of this general clinical improvement, the sudden appearance of choreiform movements, respiratory irregularities, hyperpyrexia and hypertension suggested the presence of a lesion in the brain stem and the hypothalamus. This clinical impression was largely corroborated by the postmortem examination of the brain. There is little possibility that the toxic reaction could have been caused by drugs other than streptomycin, for all other therapy was discontinued at the time that streptomycin was administered.

[11] Footnotes 8, 9 and 10.

The tremendous distention of the veins of the medulla and the small focal necroses in the nerve tissue of the medulla itself point strongly to the action of an exogenous poison which probably damaged vital centers. Furthermore, the involvement of the cortex and the basal ganglions provides an explanation of the choreiform and athetoid movements which ushered in the encephalopathy. Finally, lesions were found in the hypothalamus which may have been the cause of the hyperthermia from which the patient suffered during the last two days of her life.

The levels of streptomycin in this patient's serum were higher than any which have been recorded in our laboratory, namely 256 micrograms per cubic centimeter. Though even higher blood levels have been noted by others[12] without the appearance of cerebral symptoms, comparisons between various laboratories of levels determined by biologic methods are not strictly applicable. Cerebrospinal fluid from our patient was not examined during the administration of streptomycin, but a specimen obtained twenty-four hours after the drug was discontinued contained 25 micrograms per cubic centimeter, or 50 per cent of the blood level at that time. An assay of tissue from the brain performed by Dr. Joseph Tamura revealed no streptomycin. The significance of this finding is not clear. The explanation for the unusually high levels of streptomycin in the blood would appear to lie in the pronounced limitation of renal function which this patient exhibited clinically and indicates the necessity for the careful regulation of dosage in patients with restricted renal function.

The possibility exists that the encephalopathy may have been caused by impurities in the second batch of streptomycin, following administration of which the reaction occurred. However, the facts that central nervous lesions, particularly those involving the function of the eighth nerve, are recognized complications of the administration of streptomycin and that usually high levels of streptomycin were observed in this case suggest that the cerebral lesions were caused specifically by streptomycin.

SUMMARY

A case of fatal toxic encephalopathy, believed to be due to streptomycin, is reported. The reaction consisted of the sudden appearance of disorientation and choreiform and athetoid movements on the fifth day of treatment. These gave way to generalized convulsions, which were accompanied by rapidly appearing hyperpyrexia, tachycardia, arterial hypertension and Cheyne-Stokes respiration. Usually high levels of streptomycin were found in the blood and cerebrospinal fluid, apparently because of poor renal clearance of the drug. The presence of lesions in the brain proper suggest that the nervous manifestations of streptomycin intoxication in this case were central in origin.

Testosterone is essential for the growth and maintenance of the entire genital system apart from the interstitial cells themselves. This probably includes the tubules. It certainly includes the vas deferens, prostate, seminal vesicles, accessory urethral glands, penis and scrotum.—McCullagh, E. Perry, Bulletin of the New York Academy of Medicine, June 1948.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. Howard A. Carter, *Secretary.*

MEDIQUARTZ GERMICIDIAL ULTRAVIOLET LAMP ACCEPTABLE

Manufacturer: Medical Quartz Products Company, Subsidiary of Dallons Laboratories, 5066 Santa Monica Boulevard, Los Angeles 27.

The Mediquartz Germicidal Ultraviolet Lamp, Model 900, is a device designed to be attached to walls or ceilings and to disseminate ultraviolet radiation over large areas. It is intended for the control of air-borne bacteria and consists of a cold cathode gaseous discharge tube of a new design. The lamp has a tube of special ultraviolet-transmitting glass 16 mm. in diameter and with an exposed length of about 213 cm. When operated on a line voltage of 110, the lamp consumed 44 watts. At a distance of 12 mm. from the face of the lamp the ultraviolet energy of the lamp in microwatts per square centimeter was found to be 4,500. The intensity of radiation at a distance of 1 meter from the plane of the tube was 64 microwatts per square centimeter. The spectral distribution of the energy between 2483 and 3200 angstroms was as follows:

87 per cent between 2,483 and 2,600 angstroms
11 per cent between 2,600 and 3,000 angstroms
2 per cent between 3,000 and 3,200 angstroms

No lines below 2,482.7 angstroms were detectable; thus, the lamp meets the requirements for acceptance of disinfecting lamps. The Council accepts ultraviolet lamps for disinfecting purposes for use in hospitals, nurseries and operating rooms where the population can be controlled and where the lamps can be expected to reduce the probability of infection by air-borne bacteria. They are not acceptable for use in waiting rooms, school rooms, auditoriums, trains and similar places where persons congregate and move about at will. The Council voted to include the Mediquartz Germicidal Ultraviolet Lamp in its list of accepted devises.

THE KIDDE TUBAL INSUFFLATOR ACCEPTABLE

Manufacturer: Kidde Manufacturing Co., Inc., 35 Farrand Street, Bloomfield, N.J.

The Kidde Tubal Insufflator is a device for delivering carbon dioxide in controlled amounts and at controlled pressures into the uterine tubes for diagnostic or therapeutic purposes. The essential part of the apparatus is a gasometer which accomplishes the necessary reduction of pressure and measurement of volume. The whole apparatus is housed compactly in a portable case with a dark gray wrinkle finish. The case measures 48 by 30 by 23 cm. (19 by 12 by 9 inches) and weighs 13.4 Kg. (29 pounds, 10 ounces). The shipping weight is 18 Kg. (40 pounds). The motor actuating the kymograph draws 10 watts on a 110-115 volt alternating current. Included in the unit price of the instrument are (1) five metal refill cartridges of carbon dioxide, (2) one hundred kymograph patient-recording charts, (3) rubber tubing, (4) a bottle of recording ink and (5) a cannula. A valveless oil attachment to hold opaque medium for roentgenologic work is available as an accessory but is not included in the price of the unit.

Graduates of Schools of Osteopathy Registered by Medical Examining Boards, 1942-1947 631
Physicians Examined on the Basis of Credentials Obtained in Countries Other than the United States and Canada 632
Officers of State Boards of Medical Examiners 636
BOARDS OF EXAMINERS IN THE BASIC SCIENCES 637
NATIONAL BOARD OF MEDICAL EXAMINERS 640
EXAMINING BOARDS IN THE MEDICAL SPECIALTIES 643

This forty-sixth annual compilation of medical licensure and allied statistics by the Council on Medical Education and Hospitals covers the calendar year 1947 and includes data regarding *(a)* medical examining and licensing boards of the United States and the territories and possessions of the United States, *(b)* boards of examiners in the basic sciences, *(c)* the National Board of Medical Examiners and *(d)* examining boards in the medical specialties

The official reports which form the basis for these compilations have been contributed throughout the year by the medical licensing boards of all the states, the District of Columbia, Alaska, Hawaii, Puerto Rico and the Virgin Islands; the nineteen boards of examiners in the basic sciences; the sixteen approved examining boards in the medical specialties ; the National Board of Medical examiners, and the homeopathic medical licensing boards of Connecticut, Delaware and Maryland. The homeopathic and eclectic examining boards in Arkansas and the homeopathic board in Louisiana did not examine or license any one during the year. No physicians were registered for civilian practice in the Canal Zone.

The cooperation of the officers of the foregoing boards in making possible the vast amount of reliable information presented in the following pages has been invaluable. The Council and THE JOURNAL express their appreciation to those who have supplied these data and for other records furnished throughout the year to the office of the Council.

The tables referring to medical licensing boards include figures for the number of candidates examined for medical licensure in 1947, the numbers licensed and those who secured their first medical license in 1947 and therefore represent additions to the medical profession. There are also included other pertinent data pertaining to the regulations for medical licensure.

TABLE 1.--*Licenses Issued, 1947*

	Examination	On the Basis of Reciprocity and Endorsement	Total
Alabama	44	113	157

STATE BOARDS OF MEDICAL EXAMINERS

LICENSES ISSUED

During the year 1947 there were 14,429 licenses to practice medicine issued by the medical examining boards of the forty-eight states, the District of Columbia, Alaska, Hawaii, Puerto Rico and the Virgin Islands, as shown in table 1. Of these licenses 6,747 were issued after examination and 7,682 by reciprocity and endorsement of other state licenses or of the certificate of the National Board of Medical Examiners.

It does not follow that all physicians certified in a given year after examination were tested in that year. In twenty-four states, the District of Columbia, Alaska, Canal Zone, Hawaii, Puerto Rico and the Virgin Islands, the internship is a requisite for practice, but in several of these states the physician candidate is permitted to take the written examination before completion of the internship and, if successful, the license is withheld and dated on completion of the internship. Licenses are also withheld in some states for proof of citizenship and other technicalities. In other states the licenses of those examined in December are dated and issued in the following year. The statistics in table 1, therefore, include many who were examined in 1946 and even a few in previous years. Consequently, figures in this table will not correspond with those hereinafter given, which deal entirely with physicians examined for licensure within the year 1947.

Likewise, the figures presented in this table, particularly in the endorsement group, do not necessarily represent individuals, since the figures include persons who may have been licensed in more than one state during a given year. Neither does the total figure represent additions to the medical profession. In Tables 12, 13 and 14 (see pages 620 and 621) can be noted the number who secured licenses

for the first time and represent additions to the medical profession in the United States and its territories and possessions.

Of the 14,429 licenses to practice medicine and surgery issued in 1947, the greatest number (1,868) were issued in California. New York issued 1,645 and Illinois 904, while Ohio, Pennsylvania and Texas licensed more than 600 physicians. Sixteen states and the territories and possessions licensed fewer than 100. The fewest, 19, were licensed in Nevada.

While in 1947 the number licensed was greater than in any prewar year, there were 1,802 fewer licensed than in 1946.

The decrease in licenses issued was evident only in the group licensed without examination. Those registered after examination was 185 more than in 1946. Increases in licenses issued, however, as compared with 1946 were recorded in thirteen states and the territories and possessions as follows:

	1946	1947
Arizona	100	103
Florida	318	326
Idaho	56	71
Indiana	250	264
Kentucky	182	237
Louisiana	283	325
Maryland	343	354
Minnesota	380	420
New Mexico	59	66
North Carolina	286	336
North Dakota	30	53
South Dakota	46	53
Washington	294	301
Territories and Possessions	101	104

Totals for twelve previous years and for 1947 by all methods of licensure are included in table 3. The high figures for the years 1936 to 1941 in the annual number of licenses issued were due to the licensure of foreign graduates. In succeeding years the accelerated programs in medical schools which produced 20,662 graduates in a three year cycle increased the numbers annually licensed. The noticeable increase in the last two years reflects the migration of veteran medical officers.

In the thirteen year period shown 130,052 medical licenses have been issued, 82,049 after examination and 48,003 by *endorsement* of credentials.

CANDIDATES EXAMINED BY MEDICAL EXAMINING BOARDS

Compilations referring to those examined in 1947 by individual states, the District of Columbia, Alaska, Hawaii and Puerto Rico, indicating the numbers who passed and failed in each state, the medical school of graduation, the percentage of failures by schools and the numbers of states in which graduates of a given school were examined, are recorded in table 2. Medical schools in the United States which are no longer operating, foreign faculties of medicine, unapproved medical schools and schools of osteopathy are not listed by name, but the numbers examined in each state in these four categories are included following the figures for existing medical schools in the United States and Canada.

In the past year 7,124 applicants for licensure were examined, of whom 6,374 passed and 588, 10.5 per cent, failed. These candidates represented seventy approved medical schools in the United States, nine approved medical schools of Canada, fifteen United States medical schools now extinct, 102 faculties of medicine of other countries, six unapproved medical schools in the United States and eight schools of osteopathy. Osteopaths who were granted the privilege to practice medicine, surgery or both by medical examining boards are included in these statistics. Osteopaths who obtain the legal right to special practice by the osteopathic board are not included in these compilations.

TABLE 3.—*Licenses Issued, 1935-1947*

	Examination	Reciprocity and Endorsement	Total
1935.......	5,725	2,194	7,919
1936.......	6,275	2,773	9,048
1937.......	6,629	3,205	9,834
1938.......	6,557	2,956	9,513
1939.......	6.400	2,872	9,272
1940.......	6,289	2,866	9,155
1941.......	6,056	2,760	8,816
1942.......	6,142	2,469	8,611
1943.......	6,060	2,340	8,400
1944.......	7,062	2,596	9,658
1945.......	5,545	3,621	9,166
1946.......	6,562	9,669	16,231
1947.......	6,747	7,682	14,429
Totals..	82,049	48,003	130,052

In recent years examinations and reciprocity meetings have been scheduled at frequent times by many states to facilitate licensure and enable physicians to commence the practice of medicine without delay. Later in this study there is included a tabulation giving the schedules for all states. This effort on the part of officers of licensing boards is noteworthy, especially in view of the greatly increased numbers of physicians applying for licensure.

The 7,124 examinees represented 5,645 graduates of approved medical schools in the United States, of whom 3.1 per cent failed; 153 graduates of approved Canadian schools, 11.8 per cent of whom failed; 28 who graduated from United States medical schools now extinct, with 17.9 % failures; 601 graduates of faculties of medicine located in countries other than the United States and Canada, 52.9 per cent of whom failed; 435 graduates of of unapproved medical schools, with 42.5 per cent failures, and 262 graduates of schools of osteopathy, 18.3 per cent of whom failed.

As in table 1, the 7,124 physicians and others examined for medical licensure do not represent an equal number of individuals, since a candidate might take an examination in more than one state and is counted in each state. However, if a candidate failed more than once in a given state within the year he is counted in that state as only one failure.

The greatest number of graduates of any one school examined was 279, representing the University of Illinois College of Medicine, 218 of whom were examined in Illinois and 61 in twenty-one other states. There were 252 graduates from Northwestern University Medical School examined in thirty-one states. Fewer than 200 from other schools were represented. There were eighteen institutions in the group of schools whose graduates exceeded 100.

Twenty-three approved schools in the United States had no failures before medical licensing boards, 32 less than 5 per cent and 9 between 5 and 10 per cent. There were six schools with 10 per cent or more failures in state examinations. Failures from all existing approved schools in the United States amounted to 3.1 per cent. The percentages of failures recorded by school in table 6 which includes those who were examined by the National Board of Medical Examiners in its final examination as well as those passing state tests probably presents a more accurate analysis of the quality of the graduates of these schools on the basis of their proficiency in examination tests.

Graduates of the Medical College of Alabama, which had developed an approved four year program and graduated its first class in 1946, appeared for the first time for licensure in 1947. All the 53 graduates examined were passed. They were registered in Alabama and Florida.

Three of the five homeopathic boards in existence examined 8 candidates; Connecticut 3, Delaware 4, and Maryland 1. The homeopathic and eclectic boards in Arkansas and the homeopathic board in Louisiana did not examine any one in 1947.

Graduates of Northwestern University Medical School were examined in the greatest number of states—thirty one. Six schools had graduates examined in more than twenty states. Seven schools had graduates examined in fewer than five states.

One hundred and fifty-three graduates of the nine approved medical schools in Canada were tested for medical licensure in the United States in 1947 in twenty-two states and Alaska (table 4); 135 passed and 18, 11.8 per cent, failed. The majority appeared before the boards in California, Illinois, Maine and New York.

TABLE 4.--*Graduates of Medical Schools in Canada Examined for Licensure in the United States, 1947*

	Examined	Passed	Failed
Alabama	2	2	0
California	28	28	0
Connecticut	4	4	0
Florida	4	4	0
Georgia	1	1	0
Illinois	11	11	0
Indiana	7	7	0
Louisiana	2	2	0
Maine	11	10	1
Maryland	2	2	0
Massachusetts	9	3	6
Minnesota	9	9	0
Missouri	1	1	0
New Hampshire	4	4	0
New York	39	28	11
North Carolina	1	1	0
North Dakota	5	5	0
Ohio	1	1	0
Pennsylvania	5	5	0
Texas	1	1	0
Virginia	1	1	0
Washington	4	4	0
Alaska	1	1	0
Totals	153	135	18

The highest percentage of failures was 41.2 per cent, representing 17 graduates of Laval University Faculty of Medicine who were examined in five states. Three Canadian schools had no failures before United States licensing boards, while the other schools had more than 5 per cent failures.

Graduates of medical schools of other countries were examined by thirty-one boards. There were 601 such graduates with 318 (52.9 per cent) failures.

Twenty-eight graduates of medical schools no longer operating were tested by fifteen boards, of whom 23 passed and 5 (17.9 per cent) failed.

There were 435 graduates of unapproved medical schools examined in ten states, of whom 185, 42.5 per cent, failed. Two-hundred and sixty-two osteopaths were tested in ten states, with 18.3 per cent failures. Those registered in these two categories are discussed separately later in an analysis of these statistics.

Altogether, there were 7,124 candidates who appeared for licensure in 1947, of whom 6,374 passed and 750, 10.5 per cent, failed.

The source of applicants for licensure last year on the basis of examination is further tabulated in table 5, giving totals for six groups, namely, approved medical schools in the United States and those in Canada, schools no longer in existence, foreign faculties of medicine, unapproved medical schools and schools of osteopathy. As previously mentioned, 3.1 per cent of graduates from the schools of the United States, 11.8 per cent from Canadian schools and 17.9 per cent from extinct medical schools failed. The greatest percentage of failures represented three groups--foreign and unapproved medical schools and schools of osteopathy.

Figures which indicate actual licentiates and represent additions to the medical profession in 1947 are given later in tables 12, 13 and 14.

CONSOLIDATED EXAMINATIONS

A more accurate picture of the performance of graduates in licensure examinations than the foregoing is given by the figures which combine the results of state medical board examinations with those of part III of the National Board examinations (table 6). It can be noted that in some instances schools having a high percentage of failures before state licensing boards had few, if any, failures before the National Board. In 1947 there were 5,642 graduates of approved medical schools in the United States examined by medical licensing boards, of whom 3.1 per cent failed. In the same period 1,708 graduates of these institutions appeared for part III of the examinations of the National Board of Medical Examiners, of whom 0.9 per cent failed. In these consolidated figures for 7,350 graduates, the percentage of failures of approved medical schools in the United States was reduced to 2.3 per cent.

In calculating the percentage of failures no person was counted as a failure more than once. Eleven individuals had more than one failure during 1947. Of these, three were from United States approved schools and 8 from foreign schools.

Of the Canadian graduates, 11.8 per cent failed state board tests and 10.9 the combined tests. Only 11 graduates of foreign medical schools were admitted to the National Board's final examination, while 601 were examined by state licensing boards. Two graduates of extinct approved medical schools appeared before the National Board and 28 before state boards.

TABLE 5.—*Source of Candidates Examined for Licensure in the United States, 1947*

Medical Schools	Number Schools	Number Examined	Number Passed	Number Failed	Percentage Passed
Approved in U.S.	70	5,645	5,469	176	3.1
Approved in Canada	9	153	135	18	11.8
Extinct	15	28	23	5	17.9
Foreign	102	601	283	318	52.9
Unapproved schools	6	435	250	185	42.5
Schools of Osteopathy	8	262	214	48	18.3
Totals	210	7,124	6,374	750	10.5

No comparison can be made of these groups. The National Board does not admit to its examinations the graduates of unapproved medical schools or schools of osteopathy, and from foreign schools it admits only the graduates of the university medical schools of Great Britain and Ireland.

*Represents individuals failed.

The total of all examined before medical licensing boards as shown in this table was 7,113, of whom 6,374 passed and 739, 10.5 per cent failed. For both groups--state boards and the National Board--8,856 were examined; 8,099 passed and 757, or 8.5 per cent, failed. The total percentage of failures was not greatly reduced because of the high percentage of failures before state boards of foreign, unapproved and osteopathic graduates. Sixty-two schools in the United States and five in Canada were represented in both state and National Board examinations.

Of the Canadian graduates, 11.8 per cent failed state board tests and 10.9 per cent the combined tests. Only 11 graduates of foreign medical schools were admitted to the National Board's final examination, while 601 were examined by state licensing boards. Two graduates of extinct approved medical schools appeared before the National Board and 28 before state boards. No comparison can be made of these groups. The National Board does not admit to its examinations the graduates of unapproved medical schools or schools of osteopathy, and from foreign schools it admits only the graduates of the university medical schools of Great Britain and Ireland.

FAILURES

Failures before medical licensing boards by licentiates of 1947 are recorded in table 7. In presenting these statistics the United States is divided into two groups--the thirty-one states and the District of Columbia in which approved four year medical schools are located and the states, territories and possessions which have no four year medical school within their boundaries. The figures include the number of licentiates who failed state board examinations and were graduates of a medical school located in the state in which they were examined and, for comparison, the number of graduates licensed in a given state who obtained their professional training in schools in other states.

In general, state licensing boards require the applicant to receive a general average of 75 per cent and 60 per cent in any one subject. In case of failure in not more than two subjects, the applicant is permitted to retake an examination in those subjects within twelve months. A few states consider such persons as conditioned in the subjects in which they fail and do not report them to the office of the Council on Medical Education and Hospitals as failures. In such instances they are not considered in the calculations in this study. When their grades are raised after a successful test in the subjects in which they failed they are recorded among those who passed.

From the first group, 56 physicians failed examinations in the state in which they obtained their professional training. This occurred in nine states. New York reported 39 failures from New York schools. Twenty-three states had no failures from approved schools within their boundaries. On the other hand, seven states reported 94 failures among students who graduated from approved medical schools located in states other than the one in which they were examined. Likewise, in this group New York reported the greatest number, 80. Twenty-one states had no failures in either group, six states had failures in both groups, three states had failures from schools within their state and none from other schools while two had failures from schools in other states only.

In seventeen states having no medical schools, three reported 26 failures--Arizona, Florida and New Jersey. Fifteen of these failures occurred in Florida.

The total examined in the first group—states in which approved four year medical schools are located—was 6,181, while in the second group—states which have no approved four year medical school within their boundaries--943 were examined.

The data pertaining to licensure failures are further subdivided in table 8 by the number of candidates who were licensed after previously failing a licensing examination. The figures are presented for three categories—approved medical schools in the United States and Canada, foreign faculties of medicine and unapproved medical schools and schools of osteopathy. These groups are classified according to the number licensed after failing a state board examination

once and after two or more failures, and the table indicates whether the single and multiple failures have been in the state where licensed or elsewhere. The total number of candidates in 1947 examined and licensed or granted licenses by reciprocity or endorsement of credentials is shown as well as the total number of failures in all groups.

In 1947 there were 14,429 licenses to practice medicine issued. Of these, 662 were issued to applicants who had previously been unsuccessful before a licensing board.

In the group representing graduates of approved medical schools, 380 of those licensed had previously failed a state board examination. One hundred and forty had one failure before being licensed in a given state, and 143 were licensed after one failure in a state other than the one in which they were licensed. Of 97 who received licenses after more than one failure, 51 were registered in the original state and 35 elsewhere; 11 had failed both in the state where finally licensed and elsewhere.

This summary should be supplemented by direct communication with the

---

Some states have additional requirements for graduates of schools outside the United States and Canada.

+, indicates reciprocal or endorsement relationships have been established; .. indicates no reciprocal or endorsement relationships have been established. (See column—"At the discretion of the board.")

[1] 1st P, first papers required; ⊕, in citizenship column indicates full citizenship required.

[2] In most cases there is a small additional recording or registration fee.

[3] Year of practice after internship required.

[4] Internship accepted in lieu of one year's practice.

[5] Professional practice required.

[6] [illegible] must be graduates of a medical school approved by the

[7] [illegible]

[8] [illegible] must be within the state.

[9] [illegible] by reciprocity or examination in addition to basic science subjects of National Board.

[10] Canadian citizens are required to file first papers.

[11] Leading medical schools of Great Britain recognized.

[12] Oral examination required when original license is ten or more years old.

[13] Applicant must have resided in the state used as basis of application for one year after date on said certificate, or show two years of licensed practice in some other state.

[14] Oral examination required.

[15] Unless in practice in another state for five years.

[16] Actual practice for a period of three years immediately preceding date of application.

[17] Practical, clinical examination required.

[18] Foreign graduates only.

[19] Regular and Homeopathic boards.

[20] Reciprocity is extended to all states which accept Oregon licentiates on reciprocity basis.

[21] Regular board.

[22] Fee same as applicant's state charges if more than $50.

One hundred and fifty-seven graduates of foreign faculties of medicine and 125 graduates of unapproved medical schools and schools of osteopathy were licensed after previous failure. Among those with multiple failures in these two groups were several that had more than five unsuccessful tests before attaining licensure.

In eight states all physicians licensed last year had no failures in a state medical examination.

REGISTRATION BY RECIPROCITY AND ENDORSEMENT

The reciprocity and endorsement policies in effect in the United States, Alaska, Hawaii and Puerto Ricó are summarized in table 9. Florida, Idaho and Hawaii have not established reciprocal agreements with regard to medical licensure. Nevada, which on Aug. 5, 1946 temporarily suspended all reciprocity and endorsement privileges, reinstated this method of licensure in 1947. Idaho and Hawaii

secretary of the licensing board of the state in which the physician is interested.

---

23 Oral examination required if applicant's state requires it.

24. If the applicant passes the examination in the state from which he transfers after the completion of his internship, no practice is required.

25. License in state with which Louisiana reciprocates required.

26. Internship accepted—considered equivalent to two years' practice.

27. Fee $25.

28. Fee for license on basis of National Board certificate, $25.

29. A two year internship is accepted.

30. Diplomates of National Board not required to have been in practice for three years.

31. Same as required of Utah candidates applying for licensure.

32. Clinical examination required.

33. Reciprocity applicants only.

34. Supplemental examination required in certain cases when accepting the examination of a state with whom reciprocal relations have not been established.

35. May be licensed after a special (written) supplemental examination.

36. Fee $50.

37. For matriculants after Oct. 15, 1937.

38. Fee, $20.

39. Fee, $15.

40 Permanent license withheld until completion of citizenship.

41. Graduates of foreign medical schools effective Sept. 15, 1935. Canadian schools exempted effective Sept. 19, 1939.

42. Graduates of foreign medical schools are not accepted.

43. Graduates of foreign medical schools must have fulfilled all requirements of California prior to admittance to examination for any certificate used as basis of application to California.

44. Not applicable to citizens of Canada.

45. Not required if country in which applicant is licensed will admit to practice citizens of the United States licensed to practice in some state or upon proof of requirements similar to those required by California of graduates of foreign medical schools.

46. Not required for licensure by reciprocity.

endorse diplomates of the National Board of Medical Examiners. Florida is the only state which requires a written examination of all applicants for licensure. Those desiring licenses by reciprocity or endorsement in seventeen states, the District of Columbia and Alaska are required to obtain a certificate from the state board of examiners in the basic sciences before being eligible for medical licensure.

Twenty-eight states and Alaska have definite reciprocal agreements with specific states. Thirty states, including ten which have specific reciprocity agreements, and Puerto Rico, are given discretionary powers under the medical practice act. These thirty states will register physicians who present credentials which correspond with those required by their respective states at the time such licenses are issued. The states in which diplomates of the National Board of Medical Examiners are accepted for licensure on the basis of these credentials are also indicated.

Specific requirements, such as professional practice, oral examination and internship, are recorded, as is also the fee for a license without written examination. Citizenship prerequisites are mentioned. In some states physicians of Canadian birth are exempt from the citizenship requirement. This is indicated by footnote. Few states will accept graduates of foreign faculties of medicine on a reciprocal basis. Additional requisites or exemptions are included in footnotes.

This chart will be available in reprint form. It is helpful to physicians who are contemplating locating in another state. The facts recorded in this table are intended to present merely general statements of licensure policies. The information here given should be supplemented by direct communication with the secretary of the licensing board. A list of the executive officers in charge of medical licensure appears elsewhere in this study.

The credentials presented by physicians granted licenses to practice medicine and surgery without written examination are given in table 10. There were 7,682 so registered on the basis of licenses from other states, the District of Columbia, the territories or possessions or foreign countries, the certificate of the National Board of Medical Examiners, also the government services and special exemption. The 7,682 licensed by this method exceeded those so licensed in any previous year except 1946. The number securing licenses by reciprocity or endorsement has been steadily increasing but not to the extent which was evident in 1946 and 1947.

California issued 1,328 licenses by this method and New York registered 1,035. Three other states endorsed more than 300 candidates, namely, Massachusetts, Ohio and Texas. While the number registered was fewer than in 1946, some states issued more by this method of licensure in 1947 than in 1946. The largest number of candidates presenting the same type of credential were the 2,312 diplomates of the National Board of Medical Examiners. On the basis of this certificate 702 were licensed in New York, 272 in Massachusetts and 244 in California.

More than 450 presented licenses in Illinois and New York. The greatest number presenting a like state license were 205 Illinois licentiates who secured licenses in California. Other states registered 130 applicants holding California licenses, while that state registered on credentials 1,328 physicians from other states. In contrast with California, 540 licentiates of Illinois were licensed in other states while it endorsed 271 physicians. Arizona, Idaho, Nevada, New Mexico, North Dakota and South Dakota each had fewer than five licentiates registered in other states last year.

One hundred and seventy-eight medical officers of one of the government services received licenses by endorsement in seven states: California 56, Illinois 10, New York 1, Rhode Island 12, Texas 8, Virginia 4, and Wisconsin 87. Four physicians who were legal residents of Pennsylvania and were qualified to take the state board examination but were prevented from doing so by their service in the armed forces were licensed in Pennsylvania under the provisions of Act 132, approved April 25, 1945. Thirteen physicians were licensed in six states on credentials from one of the possessions of the United States, and sixteen on the basis of Canadian or foreign licenses. The three homeopathic boards licensed 6 physicians by reciprocity—Connecticut 3, Delaware 1 and Maryland 2.

Table 11 records the numbers from individual schools represented by the 7,682 reciprocity licentiates. Every approved medical school in the United States had graduates licensed without examination in 1947. More than 200 graduates of five schools sought such licensure. The distribution of the figures on this table reflects the movement of physicians to states other than the one in which they obtained their professional training.

One hundred and thirty-five graduates of foreign medical schools obtained endorsement of state licenses in twenty-one states and Puerto Rico, and 185 graduates of schools no longer in operation were registered in thirty-three states and Hawaii. The majority of these licentiates were graduates of Rush Medical College, which ceased to teach undergraduate medical students a few years ago. No graduates of unapproved medical schools were accepted for reciprocal registration. The figures include 111 osteopaths licensed in eight states.

The American Council on Education, representing higher education in this country, has carefully evaluated the content and quality of the many courses given in both these categories. It has issued the "Guide to the Evaluation of Educational Experiences in the Armed Forces" to assist colleges desiring to do so to award high school and college credit for specific courses taken in this program.

In addition to awarding credit for courses actually taken, as already described, there is a program for evaluating a veteran's learning experiences while in the armed forces by administering "general educational development tests" and awarding appropriate credit at the high school and college levels on the basis of the examination results, even though formal course work in the subject matter of the examination was not taken by the candidate. These are comprehensive examinations developed by the Armed Forces Institute and sponsored by the American Council on Education.

The Council on Medical Education and Hospitals has agreed to these recommendations in principle in the following statement:

California

High School and College Credit for Veterans

A. Courses at the high school and college level have been offered to members of the armed forces,

1. by correspondence through the "Armed Forces Institute," which operates in collaboration with colleges and universities, and
2. in classroom work in various schools operated for men and women in the armed services.

The American Council on Education, representing higher education in this country, has carefully evaluated the content and quality of the many courses given in both these categories. It has issued the "Guide to the Evaluation of Educational Experiences in the Armed Forces" to assist colleges desiring to do so to award proper high school and college credit for specific courses taken in this program.

B. In addition to awarding credit for courses actually taken, as described in A, there is a program for evaluating a veteran's knowledge in a given field [illegible] "General Educational Development [illegible] appropriate credit at the high school and college levels on the basis of the examination results, even though formal course work in the subject matter of the examination was not taken by the candidate. These are comprehensive examinations developed by the Armed Forces Institute and sponsored by the American Council on Education.

C. The Council on Medical Education and Hospitals of the American Medical Association (*a*) has confidence in the American Council on Education and its "Guide to the Evaluation of Educational Experiences in the Armed Forces," in the Armed Forces Institute and in the General Educational Development tests and (*b*) wishes to support sound procedures permitting veterans to commence their education in civilian institutions at a level commensurate with their ability and knowledge. Therefore the Council has decided that approved medical schools desiring to accept students at the freshman level partially on the basis of high school or college awarded credit as described in A and B will not be in conflict with the Council's regulations and policies, except that college credit for science courses requiring laboratory work should not be allowed on this basis, nor should blanket credit be allowed for military service not based on courses or examinations. Specifically, a medical college may accept, in partial fulfilment of premedical requirements:

1. High school credits, based on
   (*a*) Courses taken from the Armed Forces Institute or in service courses of the armed forces according to the "Guide to the Evaluation of Educational Experiences in the Armed Forces."
   (*b*) Performance in the General Educational Development Tests; such credit may include the equivalent of a complete high school course.

2. College credits (except in science courses requiring laboratory work, or except blanket credits for military services not based on courses or examinations), based on
   (*a*) Courses taken from the Armed Forces Institute or in service courses of the armed forces according to the "Guide to the Evaluation of Educational Experiences in the Armed Forces."
   (*b*) Performance in the General Education Development Tests.

The licensing boards of all but four states have indicated that the awarding of premedical credits under this plan by approved medical schools as the equivalent of the required premedical training will satisfy the requirement for licensure.

The Army Specialized Training and Navy V-12 premedical programs called for less than two years of college training, but in both these programs the studies were continuous and provided for the student carrying more than the normal peacetime studies per semester. Both the Army and Navy programs provided for work well in excess of the sixty semester hours constituting the normal two academic years of medical study. The information received from these states whose licensure laws include specific premedical requirements seems to indicate that there should be no licensure difficulties encountered by students whose premedical work was taken under the Army Specialized Training or Navy V-12 or comparably accelerated civilian programs.

PROFESSIONAL EDUCATIONAL REQUIREMENTS BY LICENSING BOARDS

The regulations of several of the state medical boards state in terms of hours, weeks or months the length of the medical school academic year. Similarly, some states specify in these terms the total time which must be spent in medical school. Table 16 outlines the requirements of each state in this respect. In presenting this table it should be remembered that in addition to these regulations an internship is required for licensure in some states. (See table 19.)

TABLE 17.—*Schedule of Written Examination Dates and Issuance of Licenses by Reciprocity or Endorsement of Credentials*

	Written Examination	Licenses by Reciprocity or Endorsement Issued
Alabama	Once annually	Considered by Subcommittee on application
Arizona	Quarterly	Quarterly
Arkansas	June and November	Continuously
California	Feb., June, Aug., Oct.	Six meetings annually to consider applications
Colorado	Jan. and July	Quarterly

SCHEDULE OF WRITTEN EXAMINATION DATES AND RECIPROCITY MEETINGS

In table 17 is included the current schedules of state licensing boards for examinations for medical licensure and meetings held for the issuance of licenses by reciprocity or endorsement. Examination dates and reciprocity meetings have in recent years been scheduled by many states at more frequent intervals in order to assist physicians to commence the the practice of medicine. Executive officers and members of examining boards are to be commended for their cooperation, especially in view of the increase in volume of applications in 1946 and 1947. In other states temporary permits are granted enabling physicians to immediately begin the practice of medicine. (See table 22.)

REQUIRED INTERNSHIPS

In tables 18 and 19 are listed the medical schools and licensing boards now requiring internships for the M.D. degree and licensure, respectively. Six schools in the United States and four in Canada require an internship for graduation. Although relatively few schools require the internship for the M.D. degree, this is a requirement for licensure by twenty-three state medical licensing boards, the Connecticut homeopathic medical examining board, the District of Columbia, Alaska, Canal Zone, Hawaii, Puerto Rico and the Virgin Islands. Sixteen boards require the internship to be a rotating service. The licensing boards have returned to the prewar requirement of a

one year internship but will continue to accept the nine month wartime internship. Several of the boards, however, require an additional three months of training in a military or civilian hospital. Table 20 lists these states and indicates the relationship of their requirement to the former nine month internship.

TABLE 20.—*Relationship of the Wartime Nine Month Internship to Licensure*

Accepted as Fulfilling Internship Requirement	Additional Three Months in Civilian Hospital or Military Service Required: Will Give Examination at End of Nine Months	Additional Three Months in Civilian Hospital or Military Service Required: Will Not Give Examination Until Completion of Year's Service
Alaska	Alabama[1]	Illinois[2]
Canal Zone	Delaware	New Mexico
Connecticut (homeo. board)	Dist. of Columbia	Utah
Hawaii	Iowa[1]	Virgin Islands
Idaho	New Jersey	West Virginia[3]
Michigan[3]	North Dakota	
Montana	Oregon[1]	
Nevada	Rhode Island[1]	
New Hampshire	Vermont	
Oklahoma[2]	Washington[1]	
Pennsylvania	Wisconsin	
Puerto Rico	Wyoming	
South Dakota[3]		

1. Will also give examination on completion of the medical course but withhold license until internship is completed.
2. Military medical service must be in a military hospital.
3. Three months service with United States Public Health Service acceptable.

A few of the medical schools and licensing boards maintain their own list of hospitals acceptable for intern training, but the list of approved internships compiled by the Council on Medical Education and Hospitals of the American Medical Association is generally used.

LICENSURE REQUIREMENTS FOR INTERNS AND RESIDENTS

With few exceptions physicians serving internships are not required to hold a license in the state in which the hospital where they are interning is located. The legal requirements for applicants for residency training vary considerably. In some states there is no provision for the licensure of a resident. On the other hand, a number of states consider that residents are actually in the practice of medicine and require that such individuals possess a license to practice in the states. These facts are shown in table 21.

LICENSURE ON GOVERNMENT CREDENTIALS

The medical practice acts of most states do not provide for the acceptance of government credentials as a basis for licensure without examinations. The boards of six states may issue a license without examination to a physician who has passed an examination for admission to the medical corps of the United States Army, Navy or Public Health Service. These states are California, Illinois, Texas, Utah, Virginia and Wisconsin. Legal residents of Pennsylvania who were qualified to take the state board examination but were prevented from doing so by reason of enlistment or induction into the military or naval forces of the United States in World War II are licensed without examination. In South Dakota former medical officers of World War II are exempted by law from the basic science board examination.

TABLE 21.—*Licensure Requirements for Interns and Residents*

	Licensure in State Required for Interns	Licensure in State Required for Residents

a. Physician registered with State Board may serve as intern not to exceed two years without licensure.
b. May commence residency before licensure.
c. Required by some hospitals
d. Registration with state board required.
e. May have service of two years without licensure.
f. Licensure required after one year's service.
g. May have service of three years without licensure.

RELOCATION OF PHYSICIANS

The Council on Medical Service of the American Medical Association maintains a service by which it endeavors to be of assistance to physicians desiring to relocate. This is done through close association with state and county medical societies as a voluntary effort without any attempt to direct the location of a physician. Any physician can obtain a brief but comprehensive picture of the economic status of any particular area in which he is interested from the data contained on the county summary sheets. This includes data on population, principal cities, physicians, hospitals and medical facilities and pertinent economic, social and financial information. A copy of this summary sheet is forwarded to the inquirer, and a copy of the letter to him is sent to the state and county medical society concerned.

In addition to the information contained on the summary sheets, other data are available for interested physicians. Requests for full time or part time salaried medical positions from industries, institutions and other organizations, requests from practicing physicians for associates, needs for specialists and requests of individuals for practices are cross filed and kept current by a return post card system, which keeps the Council on Medical Service informed of final locations, filling of vacancies and the securing of physicians.

Total		648

1. Reciprocity applicants
2. Government positions only

TEMPORARY PERMITS

The licensing boards of eighteen states and Puerto Rico provide for the issuance of temporary permits. These states, the length of validity of the permit and the number of permits granted during the last calendar year are shown in table 22. Alaska and Maine discontinued this service in 1947, while provisions for temporary permits were established during the year in Kansas, Nebraska, Nevada, New Jersey, North Carolina and Utah. Indiana and Nebraska grant permits only to reciprocity applicants, and Puerto Rico to physicians in government positions.

TABLE 23.--*States Requiring Annual Registration*

	Fee		Fee		Fee
Alaska	$10	Indiana	c	North Dakota	e

a. Residents, $2, Nonresidents $4. b. Residents $2, Nonresidents $10. c. Residents $5, Nonresidents $10. d. Residents $5, Nonresidents $1. e. Residents $5, Nonresidents $2. f. Residents $2. Nonresidents $5. * Biennial registration

ANNUAL REGISTRATION

Thirty states, the District of Columbia, Alaska and Hawaii require physicians to register their license annually or biennially. In table 23 are listed the licensing boards which exact this requirement. Some of these boards require such registration whether or not physicians reside in the state. The fee ranges from $1 to $10. Six states have a resident and a nonresident fee. Montana and New York require biennial registration. Indiana, Tennessee and Virginia added this regulation in 1947, while it was dropped last year in Delaware.

CANDIDATES EXAMINED, 1943-1947

In table 24 are tabulated the number of candidates examined for medical licensure in the United States and its territories and possessions for the five year period from 1943 to 1947. For each year there is recorded the number who passed and failed licensing examinations. Totals for the five years and the percentage of candidates who failed are also given.

In the five year period shown 35,882 examinations were given; 32,071 were successful tests and 3,811, 10.6 per cent, resulted in failures. New York leads in the number of examinations given. In this state 2,412 applicants were passed. More than 2,000 also were successful in California, Illinois and Pennsylvania. More than 1,000 were passed at examinations in Florida, Louisiana, Maryland, Michigan, Minnesota, Missouri, Ohio and Texas. The greatest percentage of failures, 59 per cent, occurred in Massachusetts. The majority of those failing in Massachusetts represent graduates of unapproved medical schools and graduates of schools of osteopathy. The number failing will probably decrease since the schools whose graduates were, by law, tested in this state are no longer operating. Furthermore, the State Approving Authority has ruled that students matriculating after Jan. 1, 1941 in institutions not meeting the standards of this authority will not be eligible for licensure. New York's percentage of failures, 44.3, was second highest. This state examines a considerable number of graduates of foreign medical schools, many of whom do not pass on first examination. Regulations admitting certain graduates of unapproved and osteopathic schools to its licensure examinations resulted in a high percentage of failures in 1947. Other high percentages occurred in Connecticut, Nevada and New Hampshire. Twenty-five states failed less than 5 per cent of those examined in the five year period. Twelve states had no failures. The percentage of failures has remained practically constant, the low being 9.9 per cent in 1945 and 1946 and the high 11.8 per cent in 1944.

Total Examined	8,402		6,816		5,930		7,610		7,124		35,882		
Passed	7,488		6,010		5,343		6,856		6,374		32,071		
Failed	914		806		587		754		750		3,811		
Percentage Failed	10.9		11.8		9.9		9.9		10.5		10.6		

These figures represent examinations given and not individuals. A candidate who fails more than once in a state in a given year is counted only once, but should he also fail in a succeeding year he is also counted in that year. A successful candidate securing a license in more than one state in a given year is counted in both states and likewise counted if he is passed at examinations in later years. These figures give only a fair approximation of the number of physicians added to the profession by the written examination method. Table 14, page 621 represents actual additions to the medical profession for this period.

REGISTRATION, 1904-1947

A recapitulation of the totals discussed in this study and for forty-three previous years (1904-1947) is given in table 25. This tabulation covers physicians registered by written examination and by reciprocity or endorsement of credentials. Likewise shown are the numbers who failed annually in forty-four years and the percentage of failures each year and, lastly, the total annual registration. No obvious trend in the numbers registered is evident from 1904 to 1933 except in 1918, when 4,231 were licensed, the lowest registration in forty-four years. Beginning in 1933 there was an upward trend through 1941. The decrease of more than 1200 in 1918 was due to the withdrawal of physicians and recent graduates for the armed forces in

World War I. By contrast, in 1943 the numbers increased by a similar figure over the preceding year. The increase was the result of the accelerated curriculum and efforts made to maintain civilian care at as high a level as possible and still provide for the military exigencies. In 1943 more physicians were examined than in any previous year.

The registrations in 1946 numbered almost twice as many as in 1945. Separation from service of a large number of medical officers and their return to private practice in states other than those in which they were licensed accounts in large part for this increase. This trend was again evident in 1947, although to a lesser extent. The majority of those registered by the examination method, however, represent the current graduates of a given year.

In analyzing this table it should be remembered that the figures refer to examinations given rather than to individuals examined.

GRADUATES OF APPROVED SCHOOLS AND OTHERS REGISTERED, 1922-1927

The educational fitness of physicians registered for the practice of medicine in twenty-computation of these figures, schools rated as class A and B by the Council on Medical Education and Hospitals of the American Medical Association since 1907 are classified as approved. In the column ''Others''are included individuals who graduated prior to 1907, when the first classification of schools was made, graduates of foreign faculties of medicine, Class C graduates, osteopaths given recognition by medical licensing boards and graduates of schools not approved by the Council. In 1928 the classification A, B and C by the Council was discontinued and a list of approved medical schools has since been maintained.

TABLE 25.--*Registration of Physicians, 1904-1947*

Year	Examined	Passed	Percentage Failed	Reciprocity or Endorsement	Total Registerd
1904	7,056	5,693	19.3	1,005	6,698

1930	5,571	5,255	5.7	2,366	7,621
1931	5,611	5,263	6.2	2,211	7,476
1932	5,675	5,247	7.6	1,886	7,133
1933	5,673	5,244	7.6	1,989	7,233
1934	6,145	5,628	8.4	2,161	7,789
1935	6,443	5,859	9.1	2,194	8,053
1936	6,917	6,223	10.0	2,773	8,996
1937	7,334	6,604	10.0	3,205	9,809
1938	7,461	6,589	11.7	2,956	9,545
1939	7,754	6,493	16.3	2,872	9,365
1940	7,926	6,291	20.7	2,866	9,157
1941	7,539	6,057	19.7	2,760	8,817
1942	7,222	6,119	15.4	2,469	8,588
1943	8,402	7,488	10.9	2,340	9,828
1944	6,816	6,010	11.8	2,596	8,606
1945	5,930	5,343	9.9	3,621	8,964
1946	7,610	6,856	9.9	9,669	16,525
1947	7,124	6,374	10.5	7,682	14,056

The percentage of failures gradually dropped from 19.3 in 1904, when a great many proprietary medical schools were functioning, to 5.7 in 1930. Improvements in the standards of medical education are reflected in this decrease of failures in licensing examinations. With the migration of European physicians to this country beginning in 1936 and the resultant licensure difficulties, the proportion of failures began to rise, reaching another peak of 20.7 per cent in 1940.

There were 14,056 candidates registered in 1946, of whom 13,038 (92.8 per cent) represented graduates of approved schools and 1,018 (7.2 per cent) were in the second group. In the twenty-six year period there were 198,963 registrations of approved graduates (89.1 per cent) and 24,102 others (10.8 per cent). Until the influx of foreign graduates in 1936 and the concessions made to unapproved graduates those in the second group were fewer than 1,000 annually.

GRADUATES OF UNAPPROVED SCHOOLS REGISTERED, 1942-1947

Graduates of institutions which do not meet the educational standards outlined by the House of Delegates of the American Medical Association and administered by the Council on Medical Education and Hospitals were registered in twenty states and Hawaii during the last six years. The number so registered will be found in table 27. Figures are given separately for those licensed by written examination and by endorsement of credentials. In the six years shown 1160 were registered, 1,160 by examination and 21 without written examination. New York, which has made certain concessions; Illinois, which accepts for licensure the graduates of an unappróved school located in that state, and Massachusetts licensed the largest number of graduates of unapproved schools. In the last mentioned state the institutions referred to in the table were not granted approval by the State Approving Authority. Matriculants after Jan. 1, 1941 are not eligible for licensure in Massachusetts. Regulations have become effective in Florida, Ohio and a few other states providing for licensure of unapproved graduates under certain conditions.

TABLE 26.--*Graduates of Approved Schools and Others Registered, 1922-1947*

	Graduates of Approved Schools		Others		
	Number	Per Cent of Total	Number	Per Cent of Total	Totals

GRADUATES OF SCHOOLS OF OSTEOPATHY REGISTERED BY MEDICAL EXAMINING BOARDS 1942-1947

The number of graduates of schools of osteopathy granted the privilege of practicing medicine or surgery or both by seventeen examining boards for six years (1942-1947) are given in table 28. There have been 1,192 such individuals registered, 933 by examination and and 259 without examination.

Following is a summavy of the situation in the sixteen states and the District of Columbia providing for the licensure of osteopaths by the medical examining board.

Alabama last year registered a graduate of a school of mechanotherapy.

In Colorado an osteopath receives a license to practice medicine. In Connecticut any reistered osteopath may practice either medicine or surgery or both, as the case may be, if he passes a satisfactory examination before the medical examining board. In Delaware osteopaths are licensed as " osteopathic physicians." In the District of Columbia osteopaths are granted the right to practice surgery. In Indiana the licenses issued to osteopaths under a 1945 amendment to the medical practice act authorize the holders to practice medicine and surgery. Licentiates in osteopathy prior to 1945 have now been authorized to practice osteopathy, surgery and obstetrics. In Massachusetts the medical practice act, by definition, includes osteopathy in the practice of medicine and does not differentiate the type of license issued to an osteopathic applicant. According to a law passed in Nebraska in 1943, "any

person now licensed to practice osteopathy may, if application is made prior to July 1, 1948 and upon payment of the prescribed fee, take the first regular examination given after the application is made before the Board of Examiners in Medicine....If successful he or she shall receive a license to practice medicine and surgery in the state." In New Hampshire osteopaths are granted the right to practice medicine and surgery.

New Jersey provides that osteopaths licensed prior to Nov. 1, 1941 who furnish proof prior to that date of having served for a period of two years as an intern or resident surgeon in an osteopathic or medical hospital approved by the board of medical examiners, of having completed a postgraduate course of two years in a college of osteopathy or medicine approved by the board or of having had at least three years of practice in a hospital approved by the board can be admitted to an examination in pharmacology, therapeutics and surgery and, if successful, can obtain a license to practice medicine and surgery. Since 1941 all osteopathic applicants who have met the requirements of the medical practice act have been licensed to practice medicine and surgery.

In New York a law approved April 10, 1946 provides that any osteopathic licentiate who had obtained the additional right to use instruments for minor surgical procedures and to use anesthetics, antiseptics, narcotics and biological products or any applicant who has met or shall meet all the preliminary and professional requirements as required as of September first, nineteen hundred thirty-six and has satisfactorily passed or shall satisfactorily pass the regular medical licensing examination shall be granted the right to practice medicine without limitation as defined by the statutes of the State of New York.

A law passed in Ohio in 1943 gives osteopaths who obtain their licenses under that act the right to practice osteopathic medicine and surgery. In Oregon they are granted the right to practice "in the subjects" covered by the examination, which includes surgery. The medical practice act of Texas provides for the issuing of a license to practice medicine only, and osteopaths are issued licenses unrestricted in scope. In Virginia osteopaths may obtain the right to use drugs and perform surgery with the use of instruments if they satisfy the board of medical examiners that they are qualified to do so. Wisconsin grants osteopaths the privilege to practice surgery, and in Wyoming the statutes contain no specific provision for the licensing of osteopaths. The medical practice act of the latter state provides that the certificate issued to all applicants "shall be deemed licenses to practice medicine in all branches in which the applicant has taken examination in the state."

PHYSICIANS EXAMINED ON BASIS OF CREDENTIALS OBTAINED IN COUNTRIES OTHER THAN THE UNITED STATES AND CANADA

The Council on Medical Education and Hospitals does not grade or classify medical schools outside the United States and Canada. It *does not attempt to evaluate institutions* which it is not in a position to visit to determine whether they meet the minimal essentials of an acceptable medical school as outlined by the Council. This was true even before the war.

For a period of twelve years beginning in 1926 the credentials of physicians coming from abroad were verified by the Council through official correspondence with the medical schools directly or through the diplomatic services. Prior to the onset of the war in Europe it was necessary to discontinue this effort, and on the licensing boards rests the responsibility of evaluating the credentials presented by these graduates. In the 1942 edition of the American Medical Directory a symbol in the biographic data of foreign graduates, the key number of the foreign school and the year of graduation given is the licensing board's record of the credential accepted as meeting the educational qualifications for licensure. The absence of the symbol may be interpreted to indicate that official verification is on file in the office of the Council.

A committee composed of representatives of various interested organizations has been formed to consider the problem of evaluation of foreign credentials submitted by physicians and students from foreign medical schools. This committee met in 1947 and again in 1948. No positive recommendations emerged from this meeting, but the discussions will be continued and an attempt made to obtain pertinent data pertaining to schools and educational procedures in all countries. Addresses presented at the Annual Congress on Medical Education and Licensure in February 1948 by physicians who visited medical schools in other countries and already published in THE JOURNAL[2] should be helpful to those charged with the responsibility of evaluating foreign credentials.

The requirements of candidates for medical licensure in the United States, Alaska, Hawaii and Puerto Rico on the basis of credentials obtained in countries other than the United States and Canada are given in table 29. Twenty-one states report that the holders of such *credentials are not eligible for licensure*. Eighteen states, Alaska, Hawaii and Puerto Rico require full citizenship and seven states, naturalization papers as a condition precedent to taking the examination. The District of Columbia, Indiana and Washington make no reference to citizenship. In some states the recognition or nonrecognition of such individuals is by rule of the board; in others the provision is by statute. Nine states and Alaska which will admit foreign graduates to

*Refer to chart of "Reciprocity and Endorsement Policies" for further data.

1. Certificate of National Board of Medical Examiners required.

2. Internship or one year in medical school in United States.

3. Certificate of National Board of Medical Examiners.

4. European graduates after 1939 limited to English speaking schools.

5. Residence of one year in Delaware.

6. If similar privileges are accorded licentiates of District of Columbia by licensing agency of jurisdiction from which applicant comes.

7. Senior year in an approved medical school in United States or Canada, possess the degree of Master of Public Health from an acceptable school, or satisfactorily complete a one year's assistant residency, residency or fellowship in an approved hospital.

8. Not required if country in which applicant is licensed will admit to practice citizens of the United States licensed to practice in some state or upon proof of requirements similar to those required by California of graduates of foreign medical schools.

9. Enemy aliens not accepted.

10. Application must be filed six months prior to date of examination.

11. Licensed to practice medicine and surgery in country in which school of graduation is located, otherwise required to complete senior year in approved medical school in United States.

12. Diplomates of National Board of Medical Examiners eligible.

13. License to practice medicine and surgery in the country in which the school of graduation is located. Applicants limited to University Schools of Great Britain.

14. Matriculants after January 1, 1940 not accepted.

15. At the discretion of the board.

16. Internship and graduate work.

17. Internship completed in foreign countries after July 1, 1934 not acceptable.

18. Rotating internship in approved hospital in the United States or completion of senior year in class A medical school in the United States.

19. These requirements apply also to graduates of Canadian schools.

20. No applications accepted from countries other than England (certain schools), Ireland, Scotland and Australia.

21. Provided standard was the same as California on the same date.

22. Degree from an American medical college acceptable to the Medical Council of Delaware required.

23. Diplomates of the National Board of Medical Examiners accepted. Citizenship required.

24. In lieu of internship, certificate from three graduates of applicant's medical school licensed to practice medicine in United States accepted.

25. Effective July 1, 1943.

26. Homeopathic Board requires one year internship in homeopathic hospital in the United States.

27. Matriculants of medical schools of Europe and Asia after November 19, 1941 not accepted. Graduates of medical schools of South American Republics, Mexico, and Cuba not accepted.

28. License to practice medicine and surgery in country in which school of graduation is located.

practice require a certificate from the state board of examiners in the basic sciences. In eighteen states, Alaska, Hawaii and Puerto Rico an internship in a hospital in the United States is a prerequisite. Additional qualifications of individual states are given in footnotes of the table. Table 30 presents figures relating to physicians examined on the basis of credentials obtained in countries other than the United States and Canada by licensing boards in 1947. The figures represent both American and foreign born physicians educated abroad. Ninety-nine faculties of medicine and three licensing corporations are represented. There were 601 persons examined by thirty boards in the United States, Alaska, Hawaii and Puerto Rico, of whom 283 passed and 318 (52.9 per cent) failed. Graduates of the University of Vienna (Austria) represented the largest group, 67, who were examined in twelve states, with a failure percentage of 56.7. Fewer than 40 of the graduates of any other school were tested.

TABLE 31.--*Physicians Examined on the Basis of Credentials Obtained in Countries Other Than the United States and Canada, 1930-1947*

	Number Examined	Passed	Percentage Failed
1930..........	167	92	44.9
1931..........	158	91	42.4
1932..........	182	96	47.3
1933..........	200	129	35.5
1934..........	285	170	40.2
1935..........	437	303	30.7
1936..........	588	382	35.0
1937..........	920	637	30.8
1938..........	1,164	716	38.5
1939..........	1,691	839	50.4
1940..........	2,088	948	54.7
1941..........	1,717	698	59.2
1942..........	1,630	890	45.4
1943..........	1,031	518	49.8
1944..........	691	325	53.0
1945..........	475	209	56.0
1946..........	495	221	55.3
1947..........	601	283	52.9
Total	14,520	7,547	48.0

The greatest number of these graduates examined by any one state was 387 in New York, of whom 137 passed and 250 (64.6 per cent) failed. No other state tested more than 40. Fewer than 5 were examined by sixteen states and the possessions.

Table 31 records the number of graduates of faculties of medicine abroad examined for medical licensure in the United States in eighteen years (1930-1947). In this period 14,520 were examined, of whom 7,547 passed and 48 per cent failed. The greatest number of failures occurred in 1941, when 59.2 per cent failed. At no time in this eighteen year period did fewer than 30.7 per cent fail. In 1936 the number of foreign graduates began to increase, so that in 1940 there were over three times as many tested as in 1936. Since 1940 there have been annual decreases, though the number examined in 1947 was higher than in 1946, but the annual total is still in excess of the number licensed annually prior to 1935 and before the increased migration of foreign physicians to this country from Europe.

Officers of State Board of Medical Examiners

Alabama..........	Dr. D. G. Gill, 519 Dexter Avenue, Montgomery 4.
Arizona..........	Dr. J. H. Patterson, 826 Security Building, Phoenix.
Arkansas..........	Dr. L. J. Kosminsky, Texarkana..

Puerto Rico	Mr. Luis Cuerto Coll, Parada 22, Santurce.
Virgin Islands	Dr. J. S. Moorehead, Charlotte Amalie.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Seventeen states, the District of Columbia and Alaska have adopted by legislative action basic science requirements underlying the practice of the healing art A basic science law provides for the establishment of a board of examiners and requires that each person who desires to practice the healing arts appear before the board and demonstrate his knowledge of the basic sciences. The basic science boards have no licensing powers. A certificate in the basic sciences is a prerequisite to licensure.

TABLE 32.--*States Having Basic Science Laws and Year of Enactment*

Alaska	1946
Arizona	1936
Arkansas	1929
Colorado	1937
Connecticut	1925
District of Columbia	1929
Florida	1939
Iowa	1935
Michigan	1937
Minnesota	1927
Nebraska	1927
New Mexico	1941
Oklahoma	1937
Oregon	1933
Rhode Island	1940
South Dakota	1939
Tennessee	1943
Washington	1927
Wisconsin	1925

Connecticut and Wisconsin were the first states to adopt basic science legislation. Laws were passed in these two states in 1925. Alaska was added to the group in 1946. No legislation creating a basic science law was enacted during 1947. The states, and the year of enactment of their basic science law, are recorded in table 32.

The subjects in which examinations are conducted are shown in table 33. These subjects are specified by statute.

The examining boards have no authority to add any subjects or to refrain from examining in any subject, although the laws in some instances provide for certification without examination by the endorsement of a basic science certificate issued in another state, the examinations of the National Board of Medical Examiners or the acceptance of successful examinations in the required subjects by a licensing board. On the basis of a law passed in South Dakota in 1947 medical officers may use their military record as the basis for certification. All nineteen boards examine in anatomy, pathology and physiology, seventeen examine in chemistry, fifteen in bacteriology, nine in hygiene, two in diagnosis and one in public health.

The results of examinations held and the number of certificates issued on the basis of reciprocity or endorsement during 1947 are presented in tables 34 and 35 as reported by the respective boards. A candidate in applying for a basic science certificate is not required by law to mention his school of practice. However, by checking the biographic records of physicians and medical students on file in the office of the American Medical Association and various directories it has been possible to determine the profession of the majority of candidates. Thus it has been possible to tabulate the figures in four groups; namely, physicians and medical students, osteopaths, chiropractors and unclassified applicants. The last category includes those for whom it was not possible to determine the profession represented. In Rhode Island doctors of dentistry and in Connecticut naturopaths are included in the unclassified group. It is probable that others in this unclassified group include osteopaths, chiropractors and also naturopaths who have not been identified by the reference material available.

TABLE 33.--*Subjects Included in Basic Science Examinations*

	Examinations Required in							
	Anatomy	Bacteriology	Chemistry	Diagnosis	Hygiene	Pathology	Physiology	Public Health
Alaska	x	x	x	..	x	x	x	..

Oklahoma	x	x	x	..	..	x	x	..
Oregon	x	..	x	..	x	x	x	..
Rhode Island	x	x	x	..	..	x	x	..
South Dakota	x	x	x	..	..	x	x	..
Tennessee	x	x	x	..	..	x	x	..
Washington	x	..	x	..	x	x	x	..
Wisconsin	x	..	..	x	..	x	x	..

There were 3,615 candidates examined by the nineteen boards in operation in 1947. The numbers examined in the various groups and the total examined by each board are shown in table 34. The majority (3,132) represented physicians or medical students, 147 were osteopaths, 61 chiropractors and 198 were placed in the unclassified group. Of all applicants 27.1 per cent failed. Of the physicians and medical students 23.2 per cent failed, osteopaths 34 per cent, chiropractors 68.9 per cent and unclassified 43.4 per cent. Among those who passed there were 2,405 physicians and medical students, 97 osteopaths, 19 chiropractors and 112 unclassified candidates. The basic science boards of Iowa and Florida examined the greatest number of applicants. Iowa examined 539 and Florida 512. Michigan and Minnesota tested more than 300 and Colorado, Oregon, Washington and Wisconsin more than 200. Alaska was the one board that reported no failures. The percentage of failures for physicians and medical students seems rather high, particularly when compared with the extent of failures before the state medical examining boards of the respective states.

Totals	2,405	97	19	112	2,633	771	137	13	39	960	3,593

Osteopaths were tested in Arizona, Arkansas, Colorado, Connecticut, Florida, Iowa, Michigan, Minnesota, New Mexico, Oregon, Rhode Island, Tennessee, Washington and Wisconsin. Chiropractors appeared for certification before the boards of Arizona, Connecticut, Florida, Iowa, Michigan, Minnesota, South Dakota, Washington and Wisconsin.

It is the policy of the Arizona and Minnesota boards in reporting results of its examinations to omit the names of applicants who fail examinations. The number who fail are therefore recorded only in the total column.

Fourteen boards issued 960 certificates by reciprocity, endorsement, waiver or exemption. The number of successful applicants (3,593) registered by examination and by endorsement are recorded in table 35. Included in the total certified were 3,176 physicians, 234 osteopaths, 32 chiropractors and 151 unclassified persons. All but five boards certified candidates without examination, the greatest number so certified occurred in Arizona.

In table 36 is included the number of candidates examined and certified by basic science boards for each year since and including 1927. In 1927, when five boards were functioning, there were 305 physicians examined, of whom 8.5 per cent failed and 22 other practitioners, of whom 31.8 per cent failed. By comparison in 1947 the nineteen boards in operation examined 3,132 physicians, of whom 23.2 per cent failed and 406 other practitioners, with 43.8 per cent failures.

In the twenty-one year period 28,566 physicians and medical students were examined, of whom 24,345 were successful in these examinations. In the same period 4,253 other practitioners were tested and 2,190 were successful. Of the physicians and medical students examined in twenty-one years, 14.7 per cent failed and 48.4 per cent of the other practitioners were unsuccessful. There were in this same period 6,085 physicians and 1,271 others certified without examination.

The principle of basic science legislation is to provide a means of insuring that all who seek licensure to care for sick and injured persons shall first possess a reasonable knowledge of the sciences fundamental to the healing art. The enforcement of such laws affects mostly the group classified as "other practitioners". This is particularly significant when one takes into account that the testing of individuals for basic science registration is made by nonmedical examiners. The results demonstrate that, in general, practitioners other than regular physicians are poorly equipped in the fundamentals of medicine and should not be entrusted to care for the health of the people.

Efforts are being made by the American Association of Basic Science Boards to provide information based on experience to states contemplating new basic science board legislation and to develop procedures to facilitate reciprocity arrangements. In some instances basic science certification by reciprocity is unnecessarily difficult because of otherwise unimportant differences in the laws of the various states. An analysis of basic science laws was presented by Dr. Walter L. Bierring, secretary of the Federation of State Medical Boards of the United States, before the February 1948 Annual Congress on Medical Education and Licensure.[3] In summarizing his remarks, Dr. Bierring commented on improvements that might be made in existing legislation which would produce even more effective results than are presented in the preceding paragraphs while at the same time they would facilitate the interchange of practicing physicians and relieve much of the conflict that now exists.

The present executive officer of each of the nineteen basic science boards is as follows:

OFFICIALS OF BASIC SCIENCE BOARDS

Arizona—Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Arkansas—Mr. L. E. Gebauer, 701 Main Street, Little Rock.

Colorado—Esther B. Starks, D. O., 1459 Ogden Street, Denver.

Connecticut—Mr. C. M. Bakewell, 250 Church Street, New Haven.

District of Columbia—Dr. G. C. Ruhland, 6012 E. Municipal Building, Washington.

---

[3] Federation Bulletin (March) 1948, to be published.

Florida—Dr. M. W. Emmell, University of Florida, Gainesville.
Iowa—Dr. Ben H. Peterson, Coe College, Cedar Rapids.
Michigan—Miss Eloise LeBeau, 101 N. Walnut Street, Lansing.
Minnesota—Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.
Nebraska—Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.
New Mexico—Miss Marion M. Rhea, 144 E. Marcy St., Santa Fe.
Oklahoma—Dr. Frank C. Gallagher, 813 Braniff Bldg., Oklahoma City.
Oregon—Dr. C. D. Byrne, University of Oregon, Eugene.
Rhode Island—Mr. Thomas B. Casey, 366 State Office Building, Providence.
South Dakota—Dr. G. M. Evans, Yankton.
Tennessee—Dr. O. W. Hyman, 874 Union Avenue, Memphis.
Washington—Mr. Harry C. Huse, Olympia.
Wisconsin—Mr. William H. Barber, Watson and Scott Sts., Ripon.
Alaska—Dr. C. Earl Albrecht, Box 1931, Juneau, Alaska.

NATIONAL BOARD OF MEDICAL EXAMINERS

The medical licensing boards of forty-five states, the District of Columbia, Alaska, Hawaii, Puerto Rico and the Canal Zone recognize the certificate of the National Board of Medical Examiners as an adequate qualification for a medical license. During 1945 legislation was enacted in Indiana permitting licensure without examination of National Board diplomates. In 1946 Nevada temporarily suspended acceptance of the National Board certificate, but recognition was restored in 1947. Louisiana exempts diplomates from the state examin- if they have been licensed in some other state with which Louisana reciprocates. The provisions of the medical practice laws or state regulations of the following states are such that diplomates of the National Board are required to take an oral examination: Illinois, Maine, Rhode Island, South Carolina and Wyoming. A brief supplemental written examination is required in Michigan. The National Board's certificate is not recognized by the licensing authorities of Florida, Montana and Wisconsin. The states, territories and possessions of the United States endorsing the certificate of the National Board are listed in table 37.

1. Oral examination required.
2. Brief supplemental written examination required.

The examinations of the National Board in the basic sciences are accepted in lieu of the examination in these subjects given by the basic science board of Connecticut, Iowa, Minnesota, Nebraska, Oklahoma, Tennessee and the District of Columbia.

Diplomates are admitted to the final examination of the Examining Board in England, of the Triple Qualification Board of Scotland and of the Conjoint Board in Ireland. Physicians holding the certificate of one of these licensing corporations desiring registration by the National Board are exempt from part I of its examination.

Diplomates are exempt from some of the qualifications required of the United States Public Health Service and the Mayo Foundation for Medical Education and Research.

The National Board was founded in 1915 and and the first examination for certification was given in October 1916. From that date and up to and including a test held in June 1921, eleven examinations were given and 268 candidates were certified. The results of the examinations given during this period are given in table 38.

TABLE 38.—*National Board Examinations, 1916-1921*

Date		Total Examined	Failed	Percentage Failed
October	1916	10	5	50.0

February	1921	16	5	31.3
June	1921	40	3	7.5
Totals		325	57	17.5

Since 1922 the examination has been given in three parts as follows: part I, a written examination in the basic sciences; part II, a written examination in five major clinical subjects and part III, a clinical and practical examination in six major clinical divisions and their component subjects or subdivisions. Parts I and II are given in approved medical schools throughout the country, while part III is given under the direction of local subsidiary boards in twenty-four centers at times sufficiently frequent to accommodate all eligible candidates.

Students of medical schools in the United States and Canada approved by the Council on Medical Education and Hospitals of the American Medical Association are admitted to the examinations of the National Board. In addition, graduates of the university medical schools of Great Britain and Ireland are accepted provided these graduates have been licensed to practice in the country in which the school attended is located.

The board's examinations are also accepted by many medical schools as part of their own examination and promotion procedure. At some of the schools the students are required to pass part I at the end of the second year and part II at the end of the fourth year. Other schools require that part II be passed at the end of the fourth year. Candidates who fail to to pass the National Board examinations are given a supplemental examination at most schools. The schools that require their students to take the National Board's examinations under one plan or another are Albany, Boston University, Buffalo, Duke, Emory, Georgetown, George Washington, Harvard, Long Island, New York Medical College, Ohio State, Syracuse, Tufts and Yale. In addition to the schools named there are a few others at which those students who voluntarily take and pass the National Board's examinations, either in part I or in part II, are excused from the corresponding final school examinations. This group of schools includes Colorado, Illinois, Loyola, Minnesota, Pennsylvania, Tulane and the Woman's Medical College. The National Board believes that such use of its examinations is of definite value to the board because it necessitates that the examination be kept in close step with present medical education in this country. It appreciates the responsibility that this places on its examinations as well as the confidence which the schools are placing in the fairness and quality of its examinations.

The balance of the tables enumerate the results of examinations given in parts I, II and III during 1947 and for each calendar year since 1922, including those who passed and failed examinations and those who were certified.

A candidate is eligible for part I who has met the premedical requirements and has completed successfully the first two years of work in an approved medical school. An incomplete examination is allowed candidates taking part I at the end of their second medical year in schools whose third year curriculums include courses in one or two subjects of this part. The examinations in the subjects not yet completed are therefore postponed and may be taken at any examination period after the candidate has completed them in his medical school. They are recorded in these statistics under the heading "Incomplete Examinations" and are excluded from the calculations referring to the percentage of failures. Any candidate not entitled to take an incomplete examination in part I may, if he so elects, take a divided examination by writing any four subjects at one time and the remaining two within thirteen months.

1941	1,001	954	1	46	4.6
1942	1,072	1,031	0	41	3.8
1943	1,861	1,805	0	56	3.0
1944	1,405	1,350	0	55	3.9
1945	1,599	1,565	0	34	2.1
1946	1,824	1,781	0	43	2.4
1947	1,641	1,613	0	28	1.7
Totals	21,487	20,195	46	1,246	5.8

A candidate is eligible for part III who has passed parts I and II, is in possession of the M.D. degree and has satisfactorily completed a one year internship in a hospital approved for such training by the American Medical Association or by the Canadian Medical Association, or has served in a laboratory acceptable to the National Board.

Three examinations were given in part I in 1947 and four in part II, while tests in part III were held at various times during the year.

Tables 39 and 40 record the results of examinations given in parts I and II and include candidates who fail and are reexamined during the same year and those who pass parts I and II in the same year. Thus the figures shown represent examinations conducted rather than individuals examined.

During the year 1947, 3,514 examinations were given in part I; 1,844 passed and 318, or 14.7 per cent, failed. There were 1,352 incomplete examinations given. In calculating the percentage of failures the incomplete examination figures are excluded. In part II, 1,641 examinations were held; 1,613 passed and 28, or 1.7 per cent, failed. Incomplete examinations are seldom given in part II. There were none given in 1947.

Since 1922 a total of 41,680 examinations have been given in part I and 21,487 in part

II. During this period 24,836 passed part I and 20,195 passed part II. In twenty-six years there have been 4,170 failures in part I, 14.3 per cent, and 1,246, 5.8 per cent, in part II. The increasing acceptance by medical schools of the National Board's examinations as well as the increase in the number of students in medical schools as a result of the accelerated program which is still in effect in several schools is reflected in the totals for Part I and II of the board's examinations since 1942. The greatest number of examinations were given in part I in 1944, and in part II in 1943.

Totals.........	71,747	56,724	10,061	4,962	8.0

In 1947, 1,743 tests were given in part III; 1,725 passed and 18, 1 per cent, failed. Results of examinations in this part in twenty-six years are given in table 41 and indicate that 17,228 candidates were tested, of whom 16,793 were granted the certificate of the board. Since the inception of the National Board in 1916, 17,061 certificates have been awarded. Physicians so certified are designated as diplomates and are privileged to use in any proper manner the initials D.N.B. if they so choose. The diplomates have formed a national organization entitled "The Associated Diplomates of the National Board," which meets at the time and place of the annual meetings of the American Medical Association and the Southern Medical Association. A membership emblem in the form of a gold key has been adopted. State committees have been appointed in all states.

The figures thus far presented represent examinations given. The number of individuals tested during any one year is recorded for the twenty-six year period in table 42. The classification as 'Passed" or Failed" in which more than one examination has been taken in a given year was based on the results of the last examination during the year in question. For example, if in 1947 a candidate passed part I but later in 1947 failed part II he is computed in the tabulation as having failed. On this basis figures computed indicate that there were 6,249 who took at least one of the tests of the National Board in 1947, as compared with 525 in 1922. The trend has been steadily upward. In 1947 the number of candidates was 337 greater than in the previous year. For the twenty-six year period, 71,747 individuals were examined in one or more of the annual examinations, of whom 56,724 passed, 10,061 took incomplete examinations, and 4,962, 8 per cent, failed.

The 1,725 physicians certified as diplomates last year represented sixty-two existing approved medical schools and one approved medical school now extinct in the United States, five approved schools in Canada, and eight foreign faculties of medicine (table 43). A few of the latter were graduates of the medical schools in continental Europe who had registered for the board's examinations before the limitations applied to foreign schools were put into effect.

In 1947, 2,312 diplomates were granted licenses to practice medicine on the basis of their National Board Certificate in forty-two states, the District of Columbia, Alaska, Hawaii and Puerto Rico. The number so registered by each licensing board is shown in table 44. Since the National Board was formed, 14,994 physicians have been licensed to practice medicine on the basis of their credentials from the board. In the same period 16,793 received the certificate of the board. The credential apparently was not used as a licensing medium by 1,799.

The constitution of the National Board of Medical Examiners provides for a membership of thirty representing the federal services,

TABLE 42--*National Board Examinations in Part 111, 1922-1947*

EXAMINING BOARDS IN THE MEDICAL SPECIALTIES

Examining and certifying boards have been established in sixteen specialties. The American Board of Ophthalmolgy, the first of the examining boards in the specialties, was organized in 1917. Four additional boards were organized by 1933 (Otolaryngology in 1924, Obstetrics and Gynecology in 1930, Dermatology and Syphilology in 1932 and Pediatrics in 1933). In 1934 the Council on Medical Education and Hospitals of the American Medical Association formulated minimal standards governing specialty boards. The boards then in existence were subsequently approved as well as boards formed in later years. By 1940 fifteen approved boards were in operation. The latest specialty board was added to the group in 1947 by approval of the American Board of Physical Medicine.

Three boards certify candidates in subspecialties. The American Board of Internal Medicine certifies in allergy, cardiovascular disease, gastroenterology and pulmonary diseases. The American Board of Surgery certifies in proctology, the American Board of Pediatrics certifies in allergy. Regular board certification is a prerequisite for certification in these subspecialties. This function is also approved by the Council.

The regulations of the various boards regarding their organization, personnel, purposes and requirements for certification was published in the Educational Number of THE JOURNAL in 1947[4]. There is also included the regulations of the Advisory Board for Medical Specialties. This latter board was organized in 1933-1934 and acts in an advisory capacity to the specialty boards. It also functions in close collaboration with the Council on Medical Education and Hospitals.

prior to March 1, 1947 and the number certified to March 1, 1948 respectively appear in table 45. Likewise shown in these two categories are the numbers certified in the subspecialties. A third column in this table includes the total number of living diplomates for the boards that were able to supply such figures. On March 1, 1947 there were 28,496 physicians certified by the fifteen boards in operation. During 1947 the American Board of Physical Medicine was approved and certified 86 physicians. Altogether 3,002 physicians were certified from March 1, 1947 to March 1, 1948. Up to this latter date a total of 31,498 physicians have been certified by sixteen boards. Up to March 1, 1947, 898 certificates in subspecialties were awarded and during the ensuing year 84, bringing the total in the subspecialties to 982 as of March 1, 1948.

In the specialties of internal medicine and surgery, 5,008 and 3,272, respectively, have received the certificate of these boards. These boards were organized in 1936 and 1937. Otolaryngology, organized in 1924, has certified to date 4,085, while the oldest board in existence, ophthalmology, (organized in 1917) has certified 2,657. Internal Medicine certified the greatest number in 1947—559.

TABLE 46.—*Annual Specialty Board Certifications Since 1940-1948*

Year (Ended March)	Number of Boards in Existence	Number Certified	Accumulated Totals
1940	14	.....	15,853
1941	15	2,085	17,938
1942	15	1,756	19,694
1943	15	2,172	21,866
1944	15	1,578	23,444
1945	15	1,308	24,752
1946	15	1,320	26,072
1947	15	2,424	28,496
1948	16	3,002	31,498

Table 46 gives the annual number of specialists certified by all boards for nine years and the accumulated totals. The largest number (3,002) obtained certificates in the period from March 1, 1947 to March 1, 1948. The figures shown represent the total number of cerficates issued and include the numbers of living specialists. Ten boards which were able to supply the number of living diplomates reported 890 deceased.

In THE JOURNAL[5] there was published a list of residencies and fellowships in the specialities which are acceptable to the American boards in fulfilment of the clinical training requirements.

Eleven boards recognize training with a qualified preceptor as a substitute for special clinical training. The policies of the boards toward the acceptance of such training are briefly outlined in table 47. The time credit that is allowed varies but in all instances is decided on an individual basis. This type of training is not accepted by five boards, although it is to be considered for acceptance by one of these boards.

During the year a liaison committee was formed consisting of representatives of the Council on Medical Education and Hospitals and the Advisory Board for Medical Specialties for the purpose of interchange of ideas and discussion of problems of mutual interest.

TABLE 47.—*Specialty Board Credit for Preceptorship Training*

	Credit Awarded	Preceptors Limitations			Maximum Clinical Training Credit
		Any Certified Board Member	Other Than Certified Board Members[1]	List of Preceptors Maintained	
Anesthesiology	Yes	Yes[1]	Yes[1]	No	2 years
Dermatology and Syphilology	Yes	Yes[1]	No	Yes	1 year
Internal Medicine	No	—	—	—	—
Neurological Surgery	Yes	Yes[1]	Yes[1]	No	No limit set
Obstetrics and Gynecology	Yes	Yes	Yes[1]	No	Average 6 mos. for each year of approved preceptorship.
Ophthalmology	Yes	Yes	Yes	No	No limit set
Orthopedic Surgery	Yes	Yes	No	No	See footnote 2
Otolaryngology	Yes	Yes	Yes	No	5 years
Pathology	No	—	—	—	—
Pediatrics	No	—	—	—	—
Physical Medicine	Yes	Yes[1]	Yes[1]	Yes	3 years
Plastic Surgery	Yes	Yes	No	Yes	Full Credit
Psychiatry and Neurology	No	—	—	—	—
Radiology	No	—	—	—	See footnote 3
Surgery	Yes	Yes[1]	No	No	2 years[4]
Urology	Yes	Yes[1]	No	No	3 years

1. Facilities and teacher qualifications must be approved by board.
2. Minimum of five years of training on a preceptorship will satisfy three year residency training requirement.
3. Credit for preceptor training to be considered at annual meeting, June 1948.
4. Preceptor training preceded by three years of acceptable residency training preferred.

The Fetish of Perpetual Expansion

We have unfortunately come to accept expansion as inevitable and unending. Nobody even visualizes a time when our hospitals will be emptied instead of crowded, when the conquest of disease will lead, as it logically should, to the diminution of disease. We go further and seem to assume that such expansion is something desirable in itself. We pride ourselves on the cultivation of virgin soil rather than on the harvest. Consider, for instance, the plans recently envisaged for the development of clinical photography (within certain limits a desirable thing). According to one of its enthusiastic advocates the department of the future must have a medically qualified director, an assistant director, two photographers who must also be trained nurses, a microscopist with additional training in photomicroscopy, a secretary, an instrument mechanic, a nurse, and a porter. Accommodation must consist of one large main studio, 40 by 20 ft. (12.2 by 6.1 metres), three subsidiary studios, 15 by 10 ft. (4.8 by 3 metres), three small studios for the photography of small objects, seven dark- and accessory-rooms, a secretary's office, a filming-room, a director's room, dressing cubicles, linen-cupboards, lavatories, storerooms, and a small surgery. This, we are told, would suffice for the first three years; after that extensions would be necessary. Among the users of the department would be the welfare department, which would wish to "show the return of a healthy glow to the cheeks of a convalescent." A second enthusiast tells us that medical photography must become "a subject in our medical schools on an equality with radiology." A third tells us that the staff will need a lengthy and complete training. Spaciousness, he says, would be necessary in order to counteract "the demoralizing effect of cramped quarters." But, one may ask, were Louis Pasteur, J. J. Thomson, and Gowland Hopkins demoralized by the cellars in which their best work was done?

This is perhaps an extreme case, but it illustrates an attitude of mind from which many of us suffer. Ambition in its most virtuous form impels us to raise ourselves higher from the ground on a pyramid of ever-increasing subordinates and accommodation. We measure our success by the material growth of the things which we create, forgetting meanwhile that in many human activities, such as increase of population and exploitation of new countries, this standard has had to be abandoned. We see limit, either actual or implied, in all directions; in the wide adoption of birth control, in the world shortage of many necessities, in the control of entry to the universities, and in the predetermination of the size of the new satellite towns. We can therefore hardly maintain our faith in the inevitability of perpetual expansion in the one feature of social life whose reduction is essential to the prevention of the reduction of everything else.--Roberts, Frangcon, M.D.: Where Are We Going? Medicine in a Planned Economy. *British Medical Journal*, March 13, 1948.

he absence of the compositors from their k continues. This issue of THE JOURNAL has been prepared in part by the use of Vari-Typer machines.

POSSIBLE ALLERGIC CHARACTER OF ACUTE RHEUMATIC FEVER

Periarteritis nodosa has been reproduced by Rich and Gregory[1] in the experimental animal by creating conditions similar to those of serum sickness in the human being. Cardiac lesions were seen in the sensitized animal with many of the histologic characters of the specific rheumatic granuloma. Clark and Kaplan[2] had noted in the heart and testes of 2 patients who had had serum sickness shortly before death cellular infiltrations composed of mononuclear histiocytes and showing a similar distribution to those seen in rheumatic conditions.

E. Florence McKeown[3] sensitized rabbits by either intravenous or intraperitoneal injection of 10 cc. of horse serum per kilogram of body weight. Cutaneous flushing accompanied by rise of temperature and regarded as a sign of serum sickness occurred on the twelfth to fourteenth day. At this time reaction to a skin test was positive. On the seventeenth day after the first injection of serum, the rabbits were given an intravenous injection of 1 cc. of serum. Two days later the initial large dose of serum was repeated, and the animals were killed one week later. This procedure establishes in the experimental animal conditions similar to those obtaining in serum sickness in man. The sensitization of rabbits by this method produced lesions confined to the cardiovascular system. These lesions, McKeown emphasizes, have a specific histologic structure and a specific distribution. In the heart the earliest lesion appears to be a focal necrosis of collagen. These focal necroses are found in the paravascular tissues, the interstitial septums of the myocardium and the fibrous tissue of the valve ring and valves themselves. Associated with this necrosis an inflammatory reaction develops that is composed, in the acute phase, of polymorphonuclear and eosinophilic leukocytes, which are eventually replaced by large mononuclear cells of peculiar character and by Anitschkow cells. This poses the problem as to whether this serum lesion is a reduplication of the rheumatic granuloma.

McKeown[4] traced the evolution of the primary lesion, the Aschoff nodule, as well as its age in 36 cases of rheumatic fever. The lesion appeared to be a focal necrosis of collagen, followed by emigration of polymorphonuclear leukocytes and eosinophils. Such lesions were found in the valves, valve rings, endocardium and interstitial septums of the myocardium. The histologic structure and site of the experimental lesion appear to be indentical with the specific granuloma of the naturally occurring disease. The analogy is further supported by the occurrence of endocardial and valvular lesions of similar nature. All degrees of valvulitis are present in experimental animals, and in some this is the only manifestation of a serum lesion in the heart. The serum lesion was found most frequently in the mitral valve and was not observed in the pulmonary leaflet. Where the necrosis of collagen is deep in the substance of the valve the cellular infiltration and subsequent evolution of the lesion are identical with those seen in rheumatic fever. When the necrosis is more superficial the necrotic collagen appears to be extruded onto the surface of the valve as a vegetation or to stimulate a decided proliferation of the overlying endocardial and immediately subendocardial cells, so that there is a close resemblance to the palisading of cells so often seen in the valve of the human heart.

Analysis of these valvular lesions shows their close identity with those of rheumatic valulitis in the frequent involvement of the mitral valve, the focal nature of the mitral lesion and the similarity in type of reaction. Every stage of the whole process finds its parallel in the evolution of rheumatic valvular disease. A study of the coronary arteries showed that these are impli-

eown, E.F. imental Serum Carditis and ionship t ic Fever, J. Path. & Bact. Oct.) 194

4. McKeown, E.F.: The Pathology of Rheumatic Fever, Ulster M.J., 14: 97. (Nov.) 1945.

5. MacIlwaine, Yvonne: The Relationship Between Rheumatic Carditis and Subacute Bacterial Endocarditis, J. Path. & Bact. 59: 557, (Oct.) 1947.

cated in precisely the same manner in the experimental animal as in rheumatic fever.

The investigators believe that the factor responsible for sensitization in acute rheumatism is the hemolytic streptococcus because of its frequent occurrence in the upper respiratory tract preceding an attack of acute rheumatic fever. Complete proof of this hypothesis, however, is still lacking.

The investigations of Yvonne MacIlwaine[5] throw light on the etiologic relationship between rheumatic and bacterial endocarditis. In a study of 34 cases of subacute and 12 cases of acute bacterial endocarditis she demonstrated that the myocardial Aschoff nodule is a specific reaction of the tissues to an attack of rheumatic fever and that the lesion evolves through an orderly and characteristic process of aging. A large number of the cases of acute and subacute bacterial endocarditis exhibited evidence of rheumatic arteritis. Aschoff nodules corresponding to the clinical duration of the endocarditis were observed in an even larger percentage of the cases. MacIlwaine concludes that in many cases of endocarditis lenta, and in a smaller number of cases of acute bacterial endocarditis, the bacterial lesion is superimposed on a heart which is at the time of infection the site of an active rheumatic carditis.

CANCER HEMOLYSINS

Anemia is a frequent associate of cancer. Gross[1] of the Veterans Administration Hospital, New York, has observed a direct destruction of erythrocytes by species-specific hemolysins formed or liberated by the cancer cells. Tumor extracts were made from 10 different spontaneous mammary cancers from female mice of a cancer strain and from 2 different transplanted tumors originated as mammary cancers in such females and carried through successive transplantations. Cell suspensions varying from 15 to 30 per cent were made by grinding tumor tissue in sodium chloride solution; the suspensions thus obtained were either repeatedly centrifuged or passed through a filter to form a clear sterile aqueous extract. One cubic centimeter of a 1 per cent washed suspension of red blood cells from the same strain of mice was mixed with 0.5 cc. of this extract, and the resulting mixture incubated at 37 C. for 2 1/2 to 3 hours. The tubes were then centrifuged briefly at 3,000 revolutions per minute, and the percentage of hemolysin estimated colorimetrically. Complete hemolysis was designated as 3 plus, partial hemolysis as 2 plus, 1 plus, or plus or minus, and no hemolysis as zero. Two to 3 plus hemolysis was obtained from practically all filtrates when tested in full strength. One plus hemolysis was recorded with 1:2 dilutions, and plus or minus to zero hemolysis with 1:3 dilutions of the same extract. Higher dilutions of the extracts gave negative results. Under the conditions of the experiments there were no positive readings with control extracts made from normal healthy organs such as the liver, kidney or spleen. The hemolytic action of the cancer extract was significantly less for erythrocytes prepared from heterogeneous strains of mice. Hemolytic action was not observed with rabbit, guinea pig or human erythrocytes. The cancer extract was not materially reduced in hemolytic titer by heating to 56 C. for 30 minutes. The extract, however, was completely inactivated at 100 C.

From these data the investigator concluded that strain-specific carcinoma hemolysins are at least a partial explanation of the frequent development of anemia in patients with cancer. Hemolytic tests with extracts from human cancer cells are now in progress.

Current Comment

CIVIL DEFENSE PLANNING

On March 27, 1948 the Secretary of Defense issued a memorandum to the various components of the National Military Establishment, dealing with the creation of the Office of Civil Defense Planning. This office was charged with (among other functions) preparing and submitting "to the Secretary of Defense, a program of civil defense for the United States, including a plan for a permanent federal civil defense agency which, in conjunction with the several states and their subdivisions, can undertake those peacetime preparations which are necessary to assure an adequate civil defense system in the event of a war." Mr. Russell J. Hopley, president of the Northwestern Bell Telephone Company of Omaha, was appointed director of the Office of Civil Defense Planning. Mr. Hopley is utilizing the advice and assistance of both governmental and civilian agencies to the utmost because of his belief that planning for civil defense involves every one. A medical advisory committee consisting of representation from the Armed Forces, the Public Health Service, the Childrens Bureau, the Department of Interior, the Veterans Administration, the National American Red Cross, the National Research Council, the American Medical Association, the American Dental Association, the American Public Health Association, the American Nurses Association, the American Veterans Association and the American Hospital Association has been created to assist Dr. Perrin H. Long, medical advisor to the Office of Civil Defense Planning, in drawing the plans which will cover the medical aspects of the Civil Defense Program. The medical advisory committee expects shortly to offer the broad outlines of a Medical Civil Defense Plan. Medical representation of civil defense planning groups at the state and community levels will be requested to keep in close contact with the activities of the Office of Civil Defense Planning; thus repetition and duplication of effort may be avoided and the coordination and integration of state and community plans into the over-all program will be made easier.

SARANAC SYMPOSIUM ON THE BERYLLIUM PROBLEM

A symposium held at the Saranac Laboratory for the Study of Chest Diseases at Saranac Lake, N. Y., during the week of Sept. 29, 1947 attempted to bring together available data on the health hazards resulting from exposure to the beryllium compounds. The term acute pneumonitis of beryllium workers was adopted for the acute phase, which is characterized by acute irritation of the upper respiratory tract including pharynx, trachea and bronchi, with occasional cases of acute pulmonary edema. The acute reactions have been observed only in the beryllium extraction plants where the exposure is largely due to the acid compounds of beryllium, the sulfates and the fluorides. Reactions have not been seen from contact with the metal itself. Persons so afflicted had complete clearing of the lungs, and in none had there developed the pulmonary granulomatosis observed with exposure to other compounds. All patients with acute pneumonitis had exposure either to beryllium sulfate or beryllium fluoride. Acute cases were not seen unless there had been exposure of the worker to one or the other acid compound, or to both. This fact has led some authorities to believe that beryllium should not be implicated in these acute cases because the fluorides and sulfates of many metals are similarly toxic. The chronic phase was named pulmonary granulomatosis of beryllium workers because the unit lesion is a chronic granuloma composed of proliferative cells with widely scattered giant cells occurring in the lungs. Because of associated thickening of the walls of the air sacs, interference with exchange of gases occurs, with a resulting shortness of breath on exertion and occasional deaths from failure of the right side of the heart. The radiologic and the microscopic appearance of this granulomatosis bears definite resemblance to sarcoidosis. It differs from sarcoidosis in that spontaneous remissions and disappearance of the roentgenologic shadows have not been noted and sarcoid-like lesions of bones were not observed in the beryllium variety. Another characteristic of this condition is its delayed onset, since it occurs in some cases as long as five years after termination of the exposure. In less than 2 per cent of those who are exposed do the pulmonary changes develop. This has led to the belief that an unknown factor is necessary as a trigger mechanism. Also, none of the patients so far observed have had or have contracted active tuberculosis. These chronic granulomatous lesions have occurred in three industries: (1) fluorescent lamp manufacturing, (2) beryllium-copper alloy casting and (3) sign tube shops. Despite much animal experimentation, nothing conclusive has developed. The transition from acute irritation to the chronic unit lesion has not so far been observed. A plea was made that attempts to create a threshold limit should not be made until much more is known about these materials. The greatest increased use of beryllium will probably be in alloys of copper and various other metals as a hardener. Proceedings of the symposium will be published by the Trudeau Fund as a memorial to Dr. Leroy Gardner.

CLEVELAND'S EMERGENCY MEDICAL SERVICE

For more than ten years the Academy of Medicine of Cleveland[1] has arranged to provide emergency medical service to the public at all hours, day and night, and has maintained at its own expense a twenty-four hour telephone service The effectiveness of this arrangement, which serves not only the public but the police and fire departments as well, is shown in a study of three hundred recent emergency calls, all of which, however, did not turn out to be emergencies. The average time that elapsed between a telephone call to the academy and contact with a physician was only 8.7 minutes, and that includes fourteen long calls of from 35 to 118 minutes. Not one of the long calls was a real emergency, and in each instance the circumstance surrounding the call explained the lapse of time. The average of 8.7 minutes does not show entirely the efficiency of this emergency service, as 69 per cent of the 300 calls were completed in five minutes or less and 83 per cent in ten minutes or less. The most difficult hour to obtain service was from 6 to 7 p.m., when physicians are on their way home or making calls on their own emergency patients. The length of time necessary to contact the physician was determined by the number of prior emergency calls and the desire of the patient to be served by a certain type of specialist. The telephone operator at the Academy of Medicine always asked for the name of the family physician and whether or not he had been called. A total of 77 physicians took care of the three hundred calls. In 71 per cent of 214 calls the first physician reached by the operator agreed to make the call. Certainly the income received by the 77 physicians was not their chief concern. Many patients who said that they could pay did not, some obviously could not, and a few who should pay would not. The physician sometimes was called at night into a dark neighborhood where the police or the family may have called a doctor, who was there when the academy physician arrived. Occasionally he responded to a frantic plea to find that a patient who had been injured on the way home had gone out again. Sometimes after making a call the physician found that his car had been broken into and the contents stolen. Such emergency service at night illustrates the sacrifice a doctor must make in attempting to attain the ideals of his profession. Methods similar to those used in Cleveland are now in effect in many other localities.

ORGANIZATION SECTION

Official Notes

RADIO BROADCASTS FROM ANNUAL MEETING

Owing to the fact that the Annual Meeting of the American Medical Association coincides with the Republican National Convention, arrangements for radio broadcasts are very difficult and it is impossible to announce the exact time for many broadcasts in advance.

Following is the tentative schedule of broadcasts:

Network, station, date and time are indicated when available; otherwise information must be sought in newspaper radio columns during the Annual Meeting. It may even be necessary to record some of the programs and broadcast them during the week following the meeting.

(All time is Central Daylight time, which is Chicago time.)

NBC-WMAQ	Dr. Edward L. Bortz, President of the American Medical Association; Mrs. Luther H. Kice, President of the Woman's Auxiliary, and Dr. Elmer L. Henderson, Chairman of the Board of Directors, *The American Medical Association Serves the Nation.*
CBS-WBBM	Adventures in Science Program; Dr. R. L. Sensenich, President-Elect of the American Medical Association, *Medical Preparedness.*
NBC-WMAQ	Dr. W. W. Bauer (tentative), *Convention News and Highlights.*
CBS-WBBM	Dr. Louis Bauer, Dr. Charles Gordon Heyd, Dr. Henry B. Mulholland and Dr. A.C. Ivy, *Symposium on Medical Progress.*
ABC-WENR	Dr. Roy W. Fouts, Dr. F.F. Borzell and other delegates, tape recording of interviews at opening meeting of the House of Delegates.
Mutual-WGN	Tape recording interview at the American Medical Association Scientific Exhibit with winners of Gold and Silver Medals.
WMAQ	" Elizabeth Hart Presents ": Dr. L.I. Dublin, of the Metropolitan Life Insurance Company, *Progress in Maternal and Infant Welfare.*
WCFL	Dr. V.G. Townsend, U.S. Public Health Service, Washington, D.C., interviewed by Patricia Gleason: *Occupational Hazards in Industry.*
WAAF	Mr. Oren C. Durham, of Abbott Laboratories, *Hay Fever Pollen Research.*
WAIT	Dr. David Thurber, Rochester, N. Y., *Barbiturate Poisoning.*
WEDC	Dr. Willis Sackett Knighton, New York, *Glaucoma.*
WGES	Dr. G. Foard McGinnes, Washington, D.C., *Call for Blood.*
WIND	Dr. Claire L. Straith, Detroit, *Plastic Repair of Automobile Injuries.*
WJJD	Dr. O.P.Kimball, Cleveland, *Prevention of Endemic Goiter.*
WJOL	Dr. Laurence Jones, Beverly Hills, Calif., *Low Back Pain.*
WLS	Dr. F.S. Crockett, Lafayette, Ind., Art Page's guest on the " Dinner Bell Program" at 12:30 p.m. Tuesday, June 22.

Washington Letter

(From a Special Correspondent)

June 11, 1948.

World Health Bill to White House for Signing

The bill authorizing the United States to participate in the World Health Organization has been enacted into law. The House and Senate passed Senate Joint Resolution 98 and sent it to the White House for signature prior to President Truman's departure on his western speaking tour. The House act authorized an appropriation not to exceed $1,920,000 annually as this country's contribution to the organization. The measure also exempts the United States from commitments to any special legislative action of the World Health Organization, which is a part of the United Nations and is connected with the group's Economic and Social Council.

Search for Atomic Weapon Against Cancer

A joint research program of the Atomic Energy Commission and the Office of Naval Research is studying the effects of atomic radiations on people, animals and plants, and is emphasizing a search for atomic weapons against cancer. The program includes thirty-eight different research projects to be conducted in twenty-nine schools and hospitals in this country. The studies will include exploration of the effects of atomic radiation, similar to that released by atom bombs, on living cells and will also explore causes, diagnosis and treatment of cancer. Through the use of radioactive atoms, traced by detecting devices as they move through plant and animal bodies, the research workers expect to learn more about how nerves function and nourish themselves, how plants utilize minerals and how atomic radiations alter genes, living molecules which determine hereditary characteristics.

Scientists Advise Army on Training of Specialists

The United States Army is receiving the advice of more than fifty of the nation's leading civilian scientists, it was revealed here when they met to consult with officials on recruitment, training and the use of qualified young scientists to fill three hundred and fifty specialist positions in the Army Medical Service Corps. Speakers at the two day conference included Dr. Vannevar Bush, chairman, Research and Development Board, and Brig. Gen. George E. Armstrong, Deputy Surgeon General of the Army. Major R. Roland Kuhn was appointed chief of the medical allied sciences section of the Medical Service Corps.

Committee Approves Clinic for Federal Employees

The House Appropriations Committee approved the continuation of the experimental federal health clinic in Denver, which is regarded here as indicating that governmentwide health clinics may be expected in the next two years. Committee members who expressed fear that the project may be "an attempt toward socialized medicine" were shown communications from the American Medical Association endorsing the plans. The program calls for: treatment of on the job illness and dental conditions requiring emergency attention; preemployment and periodic examinations; referral of employees to private physicians and dentists, and preventive programs relating to health.

GOVERNMENT SERVICES

ARMY

WALTER REED'S BUST IN HALL OF FAME

For the ceremony of unveiling Walter Reed's bust in the Hall of Fame on the campus of New York University, May 20, the printed program contained excerpts from letters written in longhand by Major Reed to Major J. R. Kean and to Mrs. Reed, his wife, at the time his famous experiments were under way and when the discovery of the method of transmission of yellow fever was made in 1900. The program contains also a picture of the birthplace of Major Reed in Belroi, Va.; of Camp Lazear where the experimental work was done; of the shack where some of the experiments were carried on; of the flight of the population during outbreaks of yellow fever in Newport News, Va., and other Southern states; of Reed's colleagues in the experimental work; of medals awarded; of the U. S. Army Walter Reed General Hospital, and a list of the approximately one hundred Americans whose names have been inscribed in the Hall of Fame at the university. Major Reed is the only physician in the list.

The bust of Major Reed was unveiled by his son, Major General Walter L. Reed, U. S. Army (retired). The Surgeon General of the Army, Major General Raymond W. Bliss, paid tribute to Major Reed. Dr. Wilbur A. Sawyer, executive secretary of the Organizing Committee of the fourth International Congresses on Tropical Medicine and Malaria, gave the address. Dr. Edward I. Salisbury, medical director, United Fruit Company, made the presentation and Gladys Swarthout of the Metropolitan Opera Company sang a number of selections.

MEDICAL MEETING IN KOREA

During the monthly meeting of officers of the Army medical department in Korea at the 34th General Hospital, April 21, many cases were presented during ward rounds and conferences, following which Capt. Rudolph H. Beckert read a paper on "Infections of the Lower Portion of The Urinary Tract," discussed by Lieut. Ross H. Miller, of the 382d Station Hospital. Capt. Harry C. Swanstrom, 34th General Hospital, presented a paper on "Cutaneous Medicine," discussed by Major M. B. Guthrie, dermatologic consultant Lieut. Manuel D. Altamirano, parasitologist, discussed "Intestinal Parasitic Infections in Korean Food Handlers." Capt. Chester T. Hino discussed "The Sanitary Habits of Korean Food Handlers," and Major M. B. Guthrie, "The Treatment of the Common Dermatoses." About sixty-five officers' attended, including Brig. Gen. James A. Bethea, surgeon, F. E. C.; Col. J. A. Isherood, radiologic consultant, and Lieut. Col. Rosalie B. Calhoun, director of nurses. A dinner in honor of General Bethea was held at the officer's club A bus met train 6 from Pusan to transport visiting officers to the meeting.

ARMY MEDICAL LIBRARY

The Army Medical Library has adopted the principle of free loan of microfilms for research workers. Such films may be retained for ninety days, and requests for them should be submitted on standard order forms through local libraries, research institutes or government agencies. Those who wish to keep the films permanently and those who wish photostats may obtain them at 50 cents per unit.

Representatives of the Army Medical Library have been visiting library schools to recruit candidates for positions in the Subject Cataloging Section. The qualifications include good subject knowledge of medicine and good foreign language knowledge. The salary range for this grade P-2 is $3,397.20 to $4,149.60.

SELECTED FOR SPECIAL CIVILIAN COURSES

The Surgeon General announces the selection of the following medical officers for specialized courses in civilian institutions:

Lieut. Col. Victor R. Hirschmann, training in mycology, Duke University School of Medicine, Durham, N. C.

Lieut. Col. Maurice C. Davidson, course in clinical heart disease; Harvard Medical School, Boston.

Col. Robert S. Brua, training in orthopedic surgery at Carrie Tingley Hospital for Crippled Children, Hot Springs, N. Mex.

Major Walton N. Edwards, a course in pediatrics, University of California Medical Center, San Francisco.

Lieuts. Flora Moore, A. N. C., and Blanche Zukowski, A. N. C., course in anesthesiology, St. Mary's Hospital, Galveston, Texas.

Col. George H. Donnelly and Lieut. Col. Merrill H. Judd, course in surgical anatomy, Cornell University Medical College, N. Y.

Major John E. Boysen, course in industrial medicine, Kettering Laboratory of Applied Physiology, University of Cincinnati College of Medicine.

EDGAR E. HUME PROMOTED

Col. Edgar Erskine Hume, M.C., has been promoted to the rank of brigadier general. The stars of his rank were presented in a surprise ceremony at the home of Major General David G. Barr on his arrival in China, April 27. General Hume during the recent war held the temporary rank of brigadier general; participating in the African, Sicilian and Italian campaigns. He was chief of public health in Sicily in 1943, chief of allied military division for Fifth Army from 1943 to 1945 and assistant chief of staff of the U. S. forces in Austria in 1945. He is a graduate of Centre College, Danville, Ky., and Johns Hopkins University Medical School, where he also received the degree of doctor of public health. He also holds honorary degrees from American and foreign universities.

APPOINT CHIEF OF ALLIED SCIENCES SECTION

The Surgeon General announces the appointment of Major F. Roland Kuhn as chief of the Medical Allied Sciences Section of the Medical Service Corps. Fourteen professional and scientific societies were called to the Surgeon General's office in May to advise on recruitment, training and use of qualified young scientists to fill three hundred and fifty specialists' positions in the Medical Corps of the Medical Department. Major Kuhn, who is bacteriologist at the Army Medical Research Department and Graduate School in Washington, presided. Major Kuhn received a Ph.D. at the University of Chicago in 1936 and did research there and at the University of Georgia until 1942, when he entered the Army. He served overseas in the India-Burma theater as bacteriologist with the 29th Medical Laboratory and later with the 6th Army Medical Laboratory before coming to Washington, D.C.

AWARDS AND COMMENDATIONS

Captain Frank L. Richardson

The Silver Star was awarded to Capt Frank L. Richardson, M. C., U. S. A., now of Portland, Ore., for gallantry in action in Luzon, Philippine Islands, on Dec. 8, 1941. The citation reads as follows: When large forces of enemy aircraft attacked a small airstrip on the west coast of Luzon, Capt. Richardson, surgeon, 3d Pursuit Squadron, left his regular station in a medical dugout during a strafing and bombing attack, and without regard for his personal safety proceeded to the fire-swept area where he administered medical aid to the wounded and rescued several men from burning buildings. By his indomitable spirit and willingness to risk his life for the welfare of his comrades, Captain Richardson set an example of outstanding courage and exemplified the highest traditions of military service. Dr. Richardson graduated from the University of Minnesota School of Medicine in 1937 and entered military service in February, 1941.

NAVY

RESIDENCY IN GENERAL PRACTICE

The Surgeon General of the Navy, Rear Admiral Clifford A. Swanson, announces that a new residency in general practice will be inaugurated in naval hospitals July 1. The program will cover a period of three years, during each of which medical officers will receive six months of training in general medicine and related specialties and six months in general surgery and related specialties. Instruction will be provided by the staffs of naval hospitals and by outstanding civilian visiting staffs.

NAVAL FLIGHT SURGEONS

Fifteen Naval Medical officers, three Public Health Corps officers and one medical officer of the Brazilian Air Force recently received designations as naval flight surgeons on completion of a course of study at the Naval Air Station, Pensacola, Fla. Following are the names of those designated as naval flight surgeons.

Lieut. (jg) Joseph Bader (MCR), U. S. N. R., Edinburg, Texas.

Lieut. (jg) John M. Clark (MCR), U. S. N. R., Milwaukee.

Lieut. (jg) William J. Dowling (MCR), U. S. N. R., Oklahoma City.

Lieut. (jg) Richard H. Hardin (MC), U. S. N., Rocky Mount, N. C.

Sr. Asst. Surgeon William A. Himmelsbach, U. S. P. H. S., Northhmpton, Mass.

Lieut. (jg) Bruce C. Holman (MC), U. S. N., Bainbridge, N. Y.

Lieut. (jg) Ernest L. MacQuiddy Jr. (MCR), U. S. N. R., Omaha.

Lieut. (jg) Harry B. McGee (MCR), U. S. N. R., Saginaw, Mich.

Lieut. (jg) Walter A. McLeod Jr. (MCR), U. S. N. R. St. Petersburg, Fla.

Lieut. (jg) Richard D. Nauman (MC), U. S. N., Richmond, Va.

Lieut. (jg) Paul H. Powell Jr. (MCR), U. S. N. R., Woodville, Texas.

Lieut. (jg) Thomas J. Reeves (MCR), U. S. N. R., Waco, Texas.

Lieut. (jg) Robert J. Remmer (MCR), U. S. N. R., Utica, N. Y.

Asst. Surgeon Henry C. Savage, U. S. P. H. S., Ogden, Utah.

Lieut. (jg) Donald W. Stechschulte (MCH), U. S. N. R., Windber, Pa.

Asst. Surgeon Alan F. Thometz, U. S. P. H. S., Oak Park, Ill.

Capt. Fernando R. Santos, Brazilian Air Force.

AVIATION MEDICAL EXAMINERS

Twenty-three Naval Medical Officers received their designations as aviation medical examiners at the Naval Air Station, Pensacola, Fla., after completing a twelve week course of classroom, laboratory and field work. Following are the officers who were graduated as aviation medical examiners:

Lieut. (jg) John M. Barb (MRC), U. S. N. R., Camden, N. J.

Lieut. (jg) Bruce B. Barnhill (MC), U. S. N., Corning, Ark.

Lieut. (jg) Victor F. Carey (MCR), U. S. N. R., Downsville, La.

Lieut. (jg) Louis A. Collins, Jr. (MC), U. S. N., Augusta, Ga.

Lieut. (jg) Rene A. Desjardins (MCR), U. S. N. R., Salem, Mass.

Lieut. (jg) Robert A. Driscoll (MCR), U. S. N. R., Milton, Mass.

Lieut. (jg) Joseph E. Foehr (MCR), U. S. N. R., Garden City, N. Y.

Lieut. (jg) Sidney C. Foster (MCR), U. S. N. R., South Orange, N. J.

Lieut. (jg) James F. Grant (MCR), U. S. N. R., Syracuse, N. Y.

Lieut. (jg) James R. Guthrie (MCR), U. S. N. R., Greensburg, Ind.

Lieut. Comdr. Henry B. Jenkins (MCR), U. S. N. R., Stillwater, Okla.

Lieut. (jg) Richard F. Jones (MCR), U. S. N. R., Tacoma, Wash.

Lieut. (jg) Clarence J. Kasales (MCR), U. S. N. R., Tamaqua, Pa.

Lieut. (jg) Harry T. Linger (MCR), U. S. N. R., Clarksburg, W. Va.

Lieut. (jg) Thomas G. Lyons (MCR), U. S. N. R., Stockton, Calif.

Lieut. (jg) Clyde F. Newman Jr. (MCR), U. S. N. R., Shreveport, La.

Lieut. (jg) John M. Packard (MC), U. S. N., Saranac Lake, N. Y.

Lieut. Comdr. Lloyd E. Ragan (MCR), U. S. N. R., David City, Neb.

Lieut. (jg) Holley V. Reed (MCR), U. S. N. R., Newburgh, N. Y.

Lieut. (jg) Warren G. Strout (MCR), U. S. N. R., Dexter, Maine.

Lieut. (jg) John W. Tope III (MCR), U. S. N. R., Oak Park, Ill.

Lieut. (jg) Calvin W. Tribiano (MCR), U. S. N. R., Staten Island, N. Y.

NEW REGULAR OFFICERS

The following additional members of graduating classes of medical schools have accepted appointments as lieutenants (junior grade) in the Medical Corps of the Regular Navy: Frank H. Austin Jr., Dallas, Texas; David H. Beyer, St. Paul; Robert B. Bunker, Westwood, Mass.; Frank D. Burns, Harrisburg, Pa.; LeRoy K. Branch, Lettsworth, La.; Deck E. Chandler, Salt Lake City; Frederick E. Drew, New Orleans; Raymond W. Lawrence, Staten Island, N.Y.; Ernest G. McKay, Tampa, Fla.; Wayne S. McKinley, Brookville, Pa.; John R. McLaren, Blairsville, Pa.; Deane E. McLeod, Brookville, Pa.; John C. Ready, Arlington, Mass.; Francis D. Riley, Philadelphia; William A. Snyder, Baltimore; Charles V. Treat, Jamestown, N. Y.; Harvey F. Watts, Philadelphia; Martin G. Webb Jr., Glen Olden, Pa.; John D. Wilson, Beaver, Pa., and Robert J. Zullo, Port Reading, N. J.

Medical officers on active reserve status who have recently accepted appointments in the Medical Corps of the Regular Navy include the following: Lieut. Comdr. Ralph L. Eslick, Raytown, Mo.; Lieut. (jg) John P. Colmore, Noroton Heights, Conn.; Lieut. (jg) Verne K. Harvey Jr., Alexandria, Va.; Lieut. (jg) Garner L. Lewis, Kingston, N. Y., and Lieut. (jg) James T. Proctor, Kansas City, Mo.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

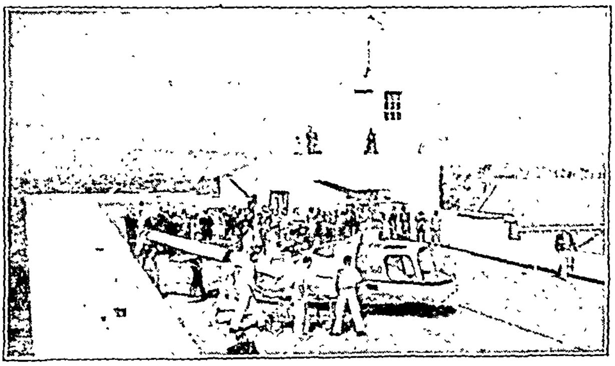
ARIZONA

New State Tuberculosis Association.—The thirty year old Arizona Antituberculosis Association was voted out of existence at the organization's annual meeting in Phoenix January 23, and the new Arizona Tuberculosis and Health Association was formed to take its place. E. W. Montgomery, Phoenix, was named president.

State Medical Election.—At the annual meeting of the Arizona State Medical Association in Phoenix, May 19-21, Dr. Harold W. Kohl, Tucson, became president. Other officers for 1948-1949 are: Drs. Robert S. Flinn, Phoenix, president-elect, Frank J. Milloy, Phoenix, secretary, and Clarence E. Yount, Prescott, treasurer. The state society formed its first Fifty Year Club. Charter members included Drs. Francis W. Allen, Tucson, Lewis A. W. Burtch, Phoenix, Timothy T. Clohessy, Phoenix, Guy H. Fitzgerald, Tucson, Delamere F. Harbridge, Phoenix, Robert N. Looney, Prescott, William R. Lyon, Tucson, E. Payne Palmer, Phoenix, Harry A. Reese, Yuma, Alexander M. Tuthill, Phoenix, and Clarence E. Yount, Prescott, They were presented bronze plaques at the dinner meeting.

CALIFORNIA

The First Hospital Heliport.—Dedication of the two hundred and fifty bed Herrick Memorial Hospital of Berkeley took place May 9; three days later its roof heliport, believed to be the first of any hospital, was opened. Formerly the Berkeley Hospital, Herrick Memorial Hospital has incorporated many of the old buildings. Modern features include a pneumatic tube system for the transfer of messages, records and drugs from department to department and a radio call system throughout the hospital. The helicopter ambulance provides an emergency facility which has been designed with elevators running directly from the heliport to the operating room. Herrick Memorial Hospital maintains an emergency hospital for citizens of Oakland, Berkeley, Albany and other adjacent areas. The heliport is expected to help solve the hospital bed shortage in rural communities.



Helicopter on hospital roof.

CONNECTICUT

Yale University Council Medical Affairs Committee.—The Yale University Council of nineteen standing committees has been created to study the major constituent parts and activities of the university and develop plans for their support. The council is composed of alumni from various sections of the country. Chairman of the committee on the Division of Medical Affairs is Reginald G. Coombe, president, board of managers, Memorial Hospital for Treatment of Cancer and Allied Diseases, New York. Other members include Thomas P. Murdock, chairman of the council, Connecticut State Medical Society, Meriden, Conn ; Barclay Robinson, Chairman, executive committee, Hartford Hospital; Robert E. Hunter, Pasadena, Calif., and Daniel C. Elkin, Whitehead Professor of Surgery, Emory University School of Medicine, Atlanta, Ga. Once a year each committee will report its findings and recommendations to the council as a whole, to be approved and transmitted to the president and the University Corporation.

ILLINOIS

Results of Hearing Survey.—Audiometric examinations given to 20,644 pupils in one hundred and eighty-eight public and parochial schools in Will County during the past seven months indicated that almost 8 per cent of all children have a hearing deficiency in one or both ears. The pilot survey was conducted by representatives of the University of Illinois College of Medicine, the Illinois Eye and Ear Infirmary, the Division of Services for Crippled Children and the Will County Department of Health, together with cooperating agencies. The children were examined by Drs. Arnold A. Grossman and Richard E. Marcus, Chicago, at seventy-seven different otologic clinics throughout the county. Those requiring further care, either to rehabilitate or to conserve hearing, were referred for definite treatment to the local otologists and general practitioners. Recommendations for specific educational requirements for those found to have handicapping hearing losses will be prepared by a special subcommittee before next September. The Will County hearing project is expected to serve as a model for future hearing conservation programs in other counties of the state.

Chicago

Dr. Ivy Appointed to Argonne National Laboratory.—Dr. Andrew C. Ivy, vice president of the University of Illinois in charge of the Chicago Professional Colleges, has been appointed to the board of the Argonne National Laboratory for a period of three years. Dr. Ivy was nominated for the position by the unanimous vote of the Council of Representatives of the participating institutions of the laboratory.

Ophthalmological Society.—The Chicago Ophthalmological Society on May 19 elected Dr. Arlington C. Krause president and Dr. J. Robert Fitzgerald secretary-treasurer. At the society's annual second Clinical Conference, November 28-December 4, special attention will be given to the pathologic and clinical aspects of glaucoma and retinal diseases, and advances in ophthalmic therapeutics. For information address Miss Maud Fairborn, 8 West Oak Street, Chicago 10.

Commemorate Founding of University Clinics.—The Alumni Association of the University of Chicago School of Medicine, commemorating the twentieth anniversary of the founding of the University Clinics, will hold its first alumni-resident staff reunion banquet at 6 p.m. Wednesday, June 23, at the Shoreland Hotel. Invitations have been sent to more than eight hundred persons. The speakers include: Chancellor Robert M. Hutchins, Drs. Lowell T. Coggeshall, Lester R. Dragstedt, Walter L. Palmer, Lucien A. Gregg and John Van Prohaska. Dinner reservations may be made through Miss Marie J. Eckert, secretary, Medical Alumni Association, 950 East 59th Street, Chicago 37.

KANSAS

William Menninger Honored.— Dr. William C. Menninger, Topeka, who was chief of the neuropsychiatric consultants' division in the Surgeon General's Office of the Army during the war, assumed office as president of the American Psychiatric Association at its one hundred and fourth meeting in Washington in May. At the same meeting Dr. Menninger was awarded the Chevalier of the French Legion of Honor presented to him by Lieut. Gen. Maurice Mathenet, military attaché of the French Embassy.

Name Head of Department of Bacteriology.— Lawrence W. Slanetz, Ph. D., will become professor of bacteriology and head of that department at the University of Kansas School of Medicine, Lawrence-Kansas City, on July 1, succeeding Dr. Noble Sherwood, head of the department for thirty years, who has passed the age of mandatory retirement from administrative duties but will continue to teach. Dr. Slanetz has been at the University of New Hampshire since 1932 and since 1938 has been bacteriologist of the state agricultural experiment station at Durham, N.H.

MAINE

State Medical Meeting.—The Maine Medical Association will hold its annual meeting at Poland Spring House, Poland Spring, June 20-22, under the presidency of Dr. Stephen A. Cobb, Sanford. A symposium on hypertension and round table discussions will take place Tuesday morning. Four general practitioner conferences, the daytime feature of the scientific program, will run from 9:30 to 11:30 a.m. and 2 to 4:00 p.m. on Monday and Tuesday. The annual dinner will be held at 7 p.m., when presentation of Fifty-Year Medals will be made. Banquet speakers will be Major General Lewis B. Hershey, Washington, D.C.

Graduate Study at Bar Harbor Laboratory.—The Roscoe B. Jackson Memorial Laboratory at Bar Harbor has established a program of graduate study which will be developed in cooperation with leading graduate schools. Students must satisfy residence and course requirements of the graduate school of their choice, and be sponsored by a staff member of the Jackson Laboratory, where at least part of the work will be done. Current research at the laboratory centers on the relation of genetics to growth processes and to the development of social behavior. Some part time assistantships at the laboratory are available. Inquiries should be addressed to Graduate Study Committee, Roscoe B. Jackson Memorial Laboratory, Box 78, Bar Harbor, Maine.

MICHIGAN

Extend Rapid Treatment Service.—The Michigan Rapid Treatment Center for venereal disease, Ann Arbor, has established a service of special benefit to physicians and patients in rural areas. Any practicing physician in Michigan may send his patient to the center for diagnosis of syphilis and for recommendations regarding treatment. The new service affords consultation not otherwise readily available in many sections of the state; it will allow the patient to be treated by his own physician in his home locality. The center has treated 10,000 patients with venereal disease referred from practicing physicians and clinics during the past four years; it now admits about 200 patients a month for treatment, has a medical officer in charge and, normally, three resident physicians. Personnel of the new consultation service will afford the benefit of their specialized knowledge to a greater share of the state's population.

NEW JERSEY

Atomic Research.—Robert Ballentine, Ph. D., of Columbia University, New York, has been appointed effective July 1, an associate research specialist in the Rutgers University Bureau of Biological Research. He will be assigned for one year to the Brookhaven National Laboratory, which is supported by the United States Atomic Energy Commission, to train personnel and to make available special technics to universities for promotion of research in radioactive isotopes. Dr. Ballentine, having received his doctor's degree from Princeton, joined the staff of Columbia University in 1942 and in 1946 took a year's leave of absence to accept the John Simon Guggenheim Memorial Foundation fellowship, working at the California Institute of Technology on organic chemical approaches to protein structure.

NEW YORK

Occupational Therapy in State Institutions.—Extension of occupational therapy to all patients whom it can benefit in the twenty-six hospitals and schools of the New York State Department of Mental Hygiene has been made possible by the provision of two hundred and nine new positions, Dr. Frederick MacCurdy, Commissioner of Mental Hygiene, has announced. The positions became available through funds recommended by Governor Dewey and approved by the legislature. The department of mental hygiene recently completed a survey to determine the occupational therapy needs of all types of patients in the state hospitals and schools. Most of the new positions are at the occupational instructor and the occupational aide levels.

New York City

Personal.—A Gold Medal was presented to Dr. Jacob M. Gershberg after twenty years of service to the International Association of Spanish Speaking Physicians at the recent banquet in his honor at the Waldorf Astoria. Among the guest speakers were ambassadors and consuls of foreign countries and the former president of Chile.

Pharmacology Research Laboratory.—The Alumni Association of the New York University College of Medicine has inaugurated a campaign to raise $250,000 to create a laboratory for research in pharmacology at the New York University-Bellevue Medical Center in the memory of the late Dr. George B. Wallace, founder of the department of pharmacology at the university, who died Jan. 15, 1948.

Standardized Antigens.—Arrangements have been made for the Department of Health to furnish standardized Venereal Disease Research Laboratory cardiolipin-lecithin antigen, Mazzini and Kolmer antigens to the twenty serologic laboratories of the Department of Hospitals, Bellevue Hospital. Technicians from the laboratories of the Department of Hospitals will be trained in the use of these antigens in the laboratories of the department of health.

Dr. Clark Appointed Dean.—Dr. Duncan W. Clark, associate dean and assistant professor of medicine, has been appointed dean of the Long Island College of Medicine, Brooklyn, effective July 1, succeeding Dr. Jean A. Curran, who has served as dean since 1937 and as president and dean since 1942. Dr. Clark is a graduate of the College, 1936, was resident physician at Kings County Hospital and in 1940-1941 held a Commonwealth Fund Fellowship at the Yale University School of Medicine, New Haven. He has been secretary of the faculty and chairman of the curriculum and internship committees and has served as director of the student health department since 1941.

OHIO

Blankenhorn in the Far East.—Dr. Marion A. Blankenhorn, professor and head of the department of medicine, University of Cincinnati College of Medicine, is on a five week teaching assignment in the Far East for the Surgeon General of the Army. The purpose of the trip is to aid in promoting and improving medical care and instruction in army medical installations in the Far Eastern Command, an assignment in line with the new program of the Army Medical Corps, which sends outstanding members of faculties abroad for short terms of intensive instruction.

Dr. Harding Appointed President of College.—Dr. George T. Harding, clinical professor of psychiatry, Ohio State University College of Medicine, and medical director of the Harding Sanitarium, Columbus, Ohio, has been elected president of the College of Medical Evangelists, Loma Linda and Los Angeles, effective September 1. Dr. Walter E. Macpherson, for six years president of the College, will become vice president and chairman of the section on medicine. Dr. Harding, a graduate of the college of Medical Evangelists in 1928, is a consultant in neuropsychiatry at the Children's Hospital, Grant Hospital and Starling-Loving University Hospital in Columbus. He is a member of the board of trustees of the Franklin County Tuberculosis Hospital in Columbus, an examiner on the American Board of Psychiatry, chairman of the Mental Hygiene Committee of the Ohio State Medical Association, a past president of the Columbus Academy of Medicine and former councillor of the Ohio State Medical Association.

OREGON

Graduate Course Schedule.—The University of Oregon Medical School, Portland, has revised its graduate course schedule to the following: September 27 to October 1, Diagnosis and Treatment of Diseases of Malignant Growth; October 18-22, General Surgery; October 25-29, Cardiology; November 1-5, Radiology; November 15-19, Gynecology; November 29 to December 2, Diseases of the Chest.

Eastern District Society Meeting.—The annual meeting of the Eastern Oregon District Medical Society will be held at Baker, June 25-26. Subjects to be discussed include: common eruptions of the hands, advances in endocrinology, roentgen examination of the upper part of the gastrointestinal tract, common anorectal complaints and infant and child feeding. At the banquet at 7 p.m., Dr. William W. Baum, Salem, will speak on " The Outlook for American Medicine."

TEXAS

Rheumatism Association.—The Texas Rheumatism Association was recently founded for the purpose of stimulating interest among physicians in problems dealing with chronic arthritis, rheumatic diseases and other allied conditions manifested by symptoms referable to the musculo-skeletal system. Dr. Howard C. Coggeshall, Dallas, was elected president and Dr. Paul J. Thomas, Dallas, Secretary.

Personals.—Charles M. Pomerat, Ph.D., director of the Tissue Culture Laboratory, University of Texas Medical Branch, Galveston, spent a week during May, at the invitation of the Mexican Government, in developing tissue culture methods in the biology and medical institutes of Mexico City.—Dr. Eric Ogden, professor of physiology, University of Texas Medical Branch, will be a guest speaker in August at the University College Hospital, London, England. Dr. Ogden will also attend the Glasgow meeting of the Physiology Society.

TENNESSEE

Grant for Research. — The U. S. Public Health Service has made available a grant of $6,000 to the University of Tennessee College of Medicine, Memphis, for a study of the relation between the motility of the pyloric sphincter and the process of gastric evacuation. This investigation is under the control of John P. Quigley, Ph. D. An additional grant of about $8,000 has been awarded for the support of studies by Richard R. Overman, Ph. D., on the water and ionic imbalances which occur in malaria and related states. About $7,000 has been allocated to Drs. Theron S. Hill and Richard R. Overman, Ph. D., for studies on the physiologic-psychiatric alterations which occur in premenstrual tension states.

WEST VIRGINIA

Organize Health Councils.—Countywide health councils have been established at Fairmont, Clay, Martinsburg and Charleston, under the sponsorship of the state department of health. In addition, a community health council is functioning at Ansted under the name, "Ansted Health Club." Another countrywide council was put in operation in Mc-country on April 1. Each council except the one located at Clay provides voluntary service to local health departments and carries on studies of health problems. The Clay council functions in matters of school health only. Five community school health councils have been established in Boone County under the direction of the public health educator attached to the county health department at Madison. Eight community-school Negro health councils have been organized in McDowell County and five in Mercer County. During the past two years, twenty-two school health councils have been organized under the supervision of the state department of education. The state health department plans to continue efforts to organize health councils on a countywide or community basis and to encourage the organization of school health councils.

WISCONSIN

State Society Purchases Home.—The State Medical Society of Wisconsin has purchased a two and one-half story brick building on Gorham Street in Madison as its new home. Space will be available for offices of the Wisconsin Veterans Medical Service agency and Wisconsin Physicians Service, as well as a meeting room for the council and society committees.

Dr. Cary's Library. — Marquette University School of Medicine, Milwaukee, has acquired the library of the late Dr. Eben J. Carey, as a gift from Mrs. Carey. The collection is made up of some volumes now out of print and books in the fields of neuroanatomy, anatomy and histology, biophysics of radiation and the relation of medicine to other sciences. Special bookplates will identify books from this collection, which will be absorbed in the regular library.

Surgical Meeting.—The Wisconsin Surgical Society held its annual meeting in Marshfield May 15 with operative clinics and papers on peritoneal lavage for uremia, surgery on diabetic patients, preparation for thyroid patients for surgery, roentgen ray in carcinoma of the breast and carcinoma of the colon and its management. The dinner speakers were Dr. Erwin R. Schmidt, Madison, " The Changing Horizon in Surgery" and Dr. Richard L. Varco, Minneapolis, "Surgical Treatment of Congenital Anomalies of the Heart and Great Vessels." Officers elected were Dr. Carl W. Eberbach, Milwaukee, president-elect, and Dr. Warner S. Bump, Rhinelander, secretary-treasurer.

GENERAL

Diplomates' National Board Meeting.—The Associated Diplomates of the National Board of Medical Examiners will hold their annual meeting at luncheon, June 24, at the Palmer House, Chicago.

Obstetric-Gynecologic Societies Meeting.— The next meeting of the board of governors of the National Federation of Obstetric-Gynecologic Societies will be held in Chicago at the Palmer House June 25 at noon.

Society Election.—The American Broncho-Esophagological Association, at their annual meeting in Atlantic City, N.J., April 7-8, elected Dr Paul H. Hollinger, Chicago, president, and Dr Edwin N. Broyles, Baltimore, secretary.

Tufts Alumni Meeting.—The Tufts Medical Alumni Association will hold a dinner meeting in Chicago, June 23, at the Windermere East Hotel, 56th Street and Hyde Park Boulevard. Dr. Harry A. Olin, Chicago, is local chairman, while Dr. John F. Conlin, Boston, is the chairman.

First Annual Meeting of General Practitioners.—The first annual meeting of the congress of delegates of the American Academy of General Practice will be held in the Sheraton Hotel, Chicago, on June 21. Dr. Paul A. Davis, Akron, Ohio, president, will preside.

Rocky Mountain Medical Conference.—August 2-4, 1949 has been selected for the next meeting of the Rocky Mountain Medical Conference to be held in Butte, Mont. The conference, purely scientific, includes the states of Colorado, Montana, New Mexico, Utah and Wyoming and meets biennially in the odd numbered years, rotating its meeting place among the five participating states.

International Congress.—The first International Congress of Physiology and Pathology of Animal Reproduction and of Artificial Insemination will be held June 21-30 in Milan, Italy. Seventeen lectures will be read and more than two hundred papers have been sent to the secretary general for discussion. All subscriptions are accepted by the secretary general of the congress in Via Bronzetti 17, Milan, Italy.

End of the Rosenwald Fund.—The Julius Rosenwald Fund, founded October 30, 1917, will close its work June 30, having fulfilled the instructions of Rosenwald to spend the principal as well as the interest by that date. It has sought, among other things, to equalize health facilities, aiding health services for Negroes, providing clinics for persons of moderate means and promoting health insurance.

Graduate Course in Thoracic Diseases.—The American Trudeau Society has arranged its second graduate course in thoracic diseases to be sponsored by the University of Colorado School of Medicine, Denver, July 19-31. The course is open to forty physicians from Arizona, Colorado, Kansas, Montana, Nebraska, New Mexico, North Dakota, South Dakota, Utah and Wyoming. The course will be under the direction of Drs. James J. Waring and H. Dumont Clark, Denver.

Alumni Dinner.—The Association of the Alumni, College of Physicians and Surgeons, Columbia University, is sponsoring a dinner in the Normandie Lounge of the Hotel Stevens, Chicago, June 23 at 7 p.m. Professor Thomas H. Davies of the University of Chicago and the Institute of Nuclear Physics will speak on "The Use of Isotopes in Biological Research." Checks for tickets should be made out to Dr. Donald G. Anderson, Treasurer, c/o the American Medical Association, 535 N. Dearborn St., Chicago 10.

Dr. Longcope Receives Medal.—The George M. Kober Medal of the Association of American Physicians was awarded to Dr. Warfield T. Longcope, Lee, Mass., formerly professor of medicine at John Hopkins University School of Medicine, Baltimore, for his contribution to medicine and medical education. The award was made at the society's annual meeting in Atlantic City, N.J., in May. Dr. Francis G. Blake, New Haven, Conn., was elected president; Dr. Walter Bauer, Boston, treasurer, and Dr. Henry M. Thomas Jr., Baltimore, secretary.

Reports on Psychiatry Advances.—The Group for Advancement of Psychiatry has prepared reports on shock therapy, the psychiatric social worker in in the psychiatric hospital, medical education, commitment procedures and public psychiatric hospitals. One copy of any report is available to any professional person on request, and additional copies may be secured from the Chairman of the Group for Advancement of Psychiatry, 3617 West 6th Street, Topeka, Kan., at 10 cents a copy, plus postage.

Medical Military Reunions.—Officers stationed at O'Reilly General Hospital during the war will hold a reunion at the Palmer House, Chicago, on June 25. Details will be available at the registration desk. The officers stationed at the Ashford General Hospital will have a reunion at the Knickerbocker Hotel, Chicago, on June 22. A reunion dinner for the medical and dental officers of the Fourth Infantry Division (Ivy Leaf Division) and their guests will be held in private dining room 14 of the Palmer House at 7:30 p.m., June 25.

Pediatric Seminar.—The Southern Pediatric Seminar, a graduate summer course in methods of diagnosis, prevention and treatment of diseases of children, will be held at Saluda, N.C., July 5-17, with Dr. Samuel F. Ravenel, Greensboro, N.C., dean. The course is designed to fit the needs of the general practitioner. Lecturers represent some of the outstanding pediatrists in the South who volunteer their services. There will be clinics, conferences, round table discussions and lectures on allergy, bronchitis, child behavior, tuberculosis, infant feeding, rheumatic fever, convulsion, diarrhea, obstetrics and poliomyelitis.

American Radium Society.—The semicentennial of the discovery of radium will be observed by the American Radium Society at the annual meeting June 20-22, in the Hotel Stevens, Chicago. Foreign guests who will participate in the program include: Francois Baclesse, Paris; Juliette Baude, Paris, Elis Berven, Stockholm; Sir Stanford Cade, B. W. Windeyer, and Constance Wood, London; Robert McWhirter, Edinburgh, and Paul Lamarque, Montpellier, France. The annual Janeway Lecture will be delivered by Sir Stanford Cade at 4:30 p.m., Monday, on "The Achievement of Radium in the Fight Against Cancer." The banquet will be at 7 p.m. Edith H. Quimby, Sc.D., New York, will speak on "Discovery of Radium."

Marriages

LIPHUS O. MURPHY Jr., Laurel, Miss., to Miss Margaret Massa of Hazelhurst March 19.

WALTER LEE BOURLAND, Memphis, Tenn., to Miss Martha Tom Wright of Paris, Tenn., March 26.

LILLARD F. BEASLEY to Miss Jane Wyatt, both of Franklin, Ky., February 22.

JOSEPH I. GARCIA Jr., Memphis, Tenn., to Miss Mary Jane Guinn of Ducktown March 16.

PHILIP C. HENNESSEE, Portland, Ind., to Miss Donna Lee of Bedford in Indianapolis February 7.

Deaths

Edward Arthur Balloch ⊕ Washington, D. C.; born in Somersworth, N. H., Jan. 2, 1857; Howard University College of Medicine, Washington, 1879; dean emeritus at his alma mater, where he served as professor of principles and practice of surgery and clinical surgery; past president of the Medical Society of the District of Columbia; fellow and founder member of the American College of Surgeons; during World War I active as medical consultant on local draft boards; for many years affiliated with the Freedmen's Hospital; in 1929 received the degree of doctor of science and was presented a testimonial bronze tablet by Howard University; received the Howard University Annual Award for distinguished postgraduate achievement; died March 2, aged 91, of cerebral thrombosis.

Reuben Adolphus MacBrayer ⊕ Southern Pines, N.C.; born in Asheville, N.C., Nov. 26, 1892 University of Pennsylvania School of Medicine, Philadelphia, 1916; member of the Medical Society of New Jersey; on active duty as a medical officer in the U. S. Army in Mexico prior to World War I; served during World Wars I and II; formerly medical director, Ciba Pharmaceutical Products, Inc., at Summit, N.J., where during the same period he was consultant in endocrinology and associate in pathology for the Overlook Hospital; at one time on the staff of the North Carolina Sanatorium for the Treatment of Tuberculosis in Sanatorium; member of the Association of Military Surgeons of the United States; died February 21, aged 55, of coronary thrombosis.

Charles Harold Avent, Memphis, Tenn.; born in Kerens, Texas, June 10, 1908; University of Tennessee College of Medicine, Memphis, 1932; member of the American Medical Association and the Southeastern Surgical Congress; fellow of the American College of Surgeons; on the faculty of his alma mater; in June 1942 entered the medical corps, Army of the United States, as a captain; service terminated with rank of lieutenant colonel in November 1945; chief surgeon for an evacuation hospital; awarded the Bronze Star for meritorious service in Belgium; affiliated with the John Gaston Hospital and the Baptist Hospital, where he died February 15, aged 39, of hypertension.

Samuel Hoberman ⊕ Malden, Mass.; born Nov. 13, 1882; George Washington University School of Medicine, Washington, D. C., 1907; for many years physician in charge of the tuberculosis clinic of the board of health; member of the American Trudeau Society; past president of the Malden Tuberculosis and Health Association; affiliated with the Malden Hospital; served as chief of the pulmonary clinic at Beth Israel Hospital, Boston; died February 18, aged 65, of carcinoma of the colon, hypertension and cerebral hemorrhage.

Samuel Humes Watson ⊕ Tucson, Ariz.; Rush Medical College, Chicago, 1899; past president of the Arizona State Medical Association and the Benton County (Ia.) Medical Society; fellow of the American College of Physicians; member of the American College of Chest Physicians and of the American Association for the Study of Allergy; specialist certified by the American Board of Internal Medicine; affiliated with the Barfield Sanatorium and St. Mary's Hospital and Sanatorium; died February 5, aged 70, of cerebral hemorrhage.

Charles Percy Aling, Minneapolis; Rush Medical College, Chicago, 1900; member of the American Medical Association; member of the staff of St. Barnabas Hospital; died January 16, aged 69, of coronary disease.

Robert Bruce Bainter, Zanesville, Ohio; Baltimore Medical College, 1893; member of the American Medical Association: affiliated with Bethesda Hospital and Good Samaritan Hospital, where he died January 20, aged 81, of fracture of the hip.

Edward Williams Barton, San Gabriel, Calif.; Medical College of Ohio, Cincinnati, 1901; served during World War I; died February 5, aged 73, of cerebral hemorrhage.

Jewell Lee Bass, Carbondale, Ill.; University of Illinois College of Medicine, Chicago, 1931; died in the Holden Hospital January 11, aged 45, of hepatic cirrhosis.

Tilman Carlisle Britt, Mount Airy, N.C.; Jefferson Medical College of Philadelphia, 1921; member of the American Medical Association; served as health officer of Surry County and of Wilmington, N.C.; died in Sanford, Fla., February 20, aged 53, of hypertension and coronary thrombosis.

James Forest Buchanan, Dallas, Texas; Baylor University College of Medicine, Dallas, 1927; member of the American Medical Association; died January 24, aged 51.

William Henry Burns ⊕ Alliance, Ohio; Cleveland Homeopathic Medical College, 1902; for many years served as health commissioner of Alliance and on the board of health; died January 20, aged 69.

Charles P. Carlisle, Dallas Texas; Gate City Medical College, Dallas, 1906; member of the American Medical Association; died January 19, aged 73.

Charles Cox Chapin, Lafayette, Ind.; College of Physicians and Surgeons, Los Angeles, 1918; member of the American Medical Association; served during World War I; medical director of Wabash Valley Sanitarium; formerly superintendent of Logansport State Hospital in Logansport; died in Home Hospital February 26, aged 55, of organic heart disease.

Alfred B. Claytor, Bedford, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; member of the American Medical Association; died January 9, aged 79, of pneumonia.

George McClave Cultra, Amarillo, Texas; University of Nebraska College of Medicine, Omaha, 1919; specialist certified by the American Board of Pediatrics; fellow of the American College of Physicians; on the staffs of the Northwest Texas and St. Anthony's hospitals, died January 4, aged 53, of cerebral hemorrhage.

Tommaso D'Alessio, South Plainfield, N.J.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1916; decorated for his gallantry during World War I; died February 27, aged 65, of coronary thrombosis and diabetes mellitus.

William A. Davis, Austin, Texas; Missouri Medical College, St. Louis, 1899; for many years state registrar of vital statistics; fellow of the American Public Health Association; formerly health officer of Fort Worth; for two terms president of the American Association of State Registration Executives; died January 27, aged 74, of myocarditis and gastric hemorrhage.

Eva A. Corell Dittmann, Cashmere, Wash.; Cleveland University of Medicine and Surgery, 1896; died January 17, aged 93, of coronary thrombosis.

Leland Pride Durant, Paso Robles, Calif.; Tulane University of Louisiana School of Medicine, New Orleans, 1942; interned at Charity Hospital in New Orleans; served a residency at Monterey County Hospital in Salinas; an officer in the medical corps of the U. S. Naval Reserve during World War II; died January 8, aged 32, of uremia and bilateral ureteral kink.

Edgar McDonell Griffith, Harrisonville, Mo.; University Medical College of Kansas City, 1911; member of the American Medical Association; director of the Cass County Health Unit; an officer serving overseas during World War I; served as county coroner and county physician; on the staffs of Menorah Hospital in Kansas City and Memorial Hospital; died February 21, aged 63, of coronary occlusion

Oscar Louis Harries, Buffalo; University of Buffalo School of Medicine, 1888; died February 22, aged 89, of fracture of neck of the femur received in fall.

James G. Harrison, McAllen, Texas, Louisville (Ky.) Medical College, 1896; died January 18, aged 74.

Joseph Jefferson Henderson, San Francisco; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; member of the American Medical Association; died January 9, aged 77, of carcinoma of the stomach.

William Elijah Hicks, Timmonsville, S. C.; Medical College of the State of South Carolina, Charleston, 1909; member of the American Medical Association; died in Florence February 8, aged 66

Julius Albin Hupert, Washington, D. C.; University of Lemberg, Austria, 1902; died February 8, aged 71, of heart disease.

John Wesley Hutchens ⊕ Portsmouth, Ohio; Miami Medical College, Cincinnati, 1905; served as health officer; on the physicians' and surgeons' staff of the Norfolk & Western, Chesapeake & Ohio and Baltimore & Ohio railways; died January 13, aged 64.

Ben Terrell Johnson, Bluffton, Ga.; Atlanta School of Medicine, 1912, died January 19, aged 59.

Willis H. Kimball, San Diego, Calif.; Medical School of Maine, Portland, 1891; died February 15, aged 81.

Joseph Davis Lehman, Philadelphia; Jefferson Medical College of Philadelphia, 1902; also a graduate in pharmacy; member of the American Medical Association; at one time on the faculty of his alma mater; for many years physician for the board of health and chief of staff at Memorial Hospital; died February 22, aged 74.

John Lawrence Lund, Perth Amboy, N.J.; Long Island College Hospital, Brooklyn, 1891; on the local board of health for one term; formerly city physician; during World War I served as a captain in the medical corps of the U. S. Army; formerly on the staff of Perth Amboy General Hospital; died February 21, aged 80, of heart disease.

James Donald McKay ⊕ Marion, Ind.; Trinity Medical College, Toronto, Canada, 1895; served on the staffs of the Marion General and Veterans Administration hospitals; died February 18, aged 78, of coronary occlusion.

John F. McMath, Americus, Ga.; University of Georgia Medical Department, Augusta, 1889; died January 28, aged 92.

Grace Milliken, Dedham, Mass.; Tufts College Medical School, Boston, 1926; member of the American Medical Association; died in the New England Hospital for Women and Children in Boston, January 19, aged 74, of probable pulmonary embolism and a fractured hip received in an accident.

Robert Edgar Mitchell, Richmond, Va.; Medical College of Virginia, Richmond, 1913; also a graduate in pharmacy; member of the American Medical Association and of the Richmond Academy of Medicine; affiliated with the Medical College of Virginia Hospital, Johnston-Willis Hospital and the Stuart Circle Hospital; died February 21, aged 63, of cerebral hemorrhage.

James Hunt O'Connor, San Francisco; Cooper Medical College, San Francisco, 1895; member of the American Medical Association; fellow of the American College of Surgeons; formerly chief surgeon for the Market Street Railway; served on the staff of St. Francis Hospital; for many years on the staff of the Southern Pacific Hospital, where he died February 2, aged 78.

Thomas Hunt O'Connor ⊕ San Francisco; Cooper Medical College, San Francisco, 1908; also a graduate in pharmacy; in 1933 elected to the board of trustees of St. Francis Hospital, where during the past eight years he served as first vice president and chief of the department of surgery; died February 4, aged 67, of cerebral hemorrhage.

Gustaf Adolf Oredson, Hoquiam, Wash.; College of Medical Evangelists, Loma Linda and Los Angeles, 1938; member of the American Medical Association and of the California Medical Association; certified by the National Board of Medical Examiners; served overseas during World War II; affiliated with St. Joseph Hospital in Aberdeen; died February 15, aged 37, of heart disease.

Henry Leon Picard, Philadelphia; Jefferson Medical College of Philadelphia, 1896; served on the staffs of the Lankenau, St. Mary's and Jefferson hospitals; died January 15, aged 72.

Mardell Yates Pope ⊕ Monticello, Ark.; Jefferson Medical College of Philadelphia, 1893; an Affiliate Fellow of the American Medical Association; served during World War I; died January 22, aged 78, of myocarditis.

Anthony Domenico Semisa, New York; New York Homeopathic Medical College and Flower Hospital, New York, 1913; member of the American Medical Association; died January 8, aged 63.

Furman Thomas Simpson, Westminster, S. C.; University of Maryland School of Medicine, Baltimore, 1909; member of the American Medical Association; veteran of World War I; served as chairman of the local board of health and as county health officer; died January 29, aged 65, of heart disease.

Arthur Bushnell Smith, San Diego, Calif.; Cleveland University of Medicine and Surgery, 1897; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc., and of the American College of Radiology; died January 11, aged 74, of uremia, nephritis and chronic prostatitis.

Anthony Edward Sojewicz, Syracuse, N.Y.; Syracuse University College of Medicine, 1934; member of the American Medical Association; served during World War II; on the staff of Onondaga General Hospital, where he died February 18, aged 39, of cerebral hemorrhage.

Harol Steele, St. Louis; Universidad Nacional Facultad de Medicina, Mexico, D. F., 1941; member of the American Medical Association; on the staff of Missouri Pacific Hospital, where he died February 5, aged 44, of heart disease.

Eunice Rand Stoops, Oakland, Calif.; American Medical Missionary College, Battle Creek and Chicago, 1902; died January 26, aged 71.

Benjamin Lansing Ten Eyck ⊕ Major, U. S. Army, retired, New Rochelle, N.Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1885; served in the U. S. Army from 1889 to 1903, when he was retired for disability; veteran of the Spanish-American War; died February 4, aged 85, of arteriosclerosis.

Edith Rebecca Hornberger Wolf, Lakeland, Fla.; Cleveland University of Medicine and Surgery, 1896; formerly a medical missionary in Africa; died February 10, aged 76.

Tetraethylammonium as Regulator of Vegetative Nervous System

Professors C. Lian and G. Bergamo have obtained fairly lasting results in the treatment of arterial hypertension, angina pectoris, Raynaud's Disease and arteritis obliterans by tetraethylammonium; contrary to other reports, uncomfortable reactions to this drug were infrequent. Five cubic centimeter ampules of tetraethylammonium in a 10 per cent solution were used intramuscularly and often associated with a substance prolonging the *drug's action: "subtosan"·(polyvinyl pyrrolindina)* in 25 per cent solution. The authors found that tetraethylammonium is a great regulator of the vegetative nervous system: the injection of this drug in an animal anesthetized by morphine initiates an acceleration of the cardiac frequency up to the normal; to the contrary, in an animal anesthetized with barbiturates an injection slows the heartbeat to normal. The effect remains the same when the modifications of the cardiac rhythm have been obtained by the preganglionic excitation of the cardiac nerves. The authors have employed this drug in human beings also and reported their results to the "Societe Medicale des Hopitaux de Paris," April 9, 1948. In a young woman with tachycardia due to sympathetic hypertonia the intravenous injection of one ampule of the drug for a few days progressively diminished the pulse rate from 140 to 80 a minute, in another case from 130 to 110. Inversely, in 2 asthmatic and brachycardiac patients repeated injections of the drug induced a progressive acceleration of the pulse: in the first case from 58 to 75, in the second from 60 to 72. In several vagotonic patients they observed that the slowing down of the heart, initiated by compressing the eyeball does not occur after a previous injection of one ampule of this drug; inversely, in sympatheticotonic patients the same process caused, after injection of one ampule, a normal slowing down of the cardiac frequency. In 1 patient in whom intensive ephedrine therapy had no effect on frequent pauses of the heart due to sinoauricular block, the intravenous injection of one ampule of tetraethylammonium caused the block to disappear and the rhythm to increase from 38 to 65 pulsaions; however, forty-five minutes after the injection the intermittent block and bradycardia reappeared. The authors are of the opinion that this drug would have a favorable effect against acute edema of the lung.

A Study of Delinquent Children

Dr. M. Heuyer has *made a study of the influence* of the war and the period of occupation on the psychology of children. The intellectual level of children has not been impaired by war, and mental debility has not increased. The author made these conclusions following a census of abnormal children, begun in 1937 and pursued during the war. The study was based on the Gilles nonverbal test and comprised the mental analysis of 100,000 children of twenty-five different regions. The educational level, which had fallen during the war, has again risen to the prewar level. The number of vagabond children entrusted to private institutions has risen from 492 in 1938 to 2,505 in 1944. Children's gangs have been rare in France. The number of underage offenders appearing before the courts for the whole of France increased from 11,788 in 1937 to 32,100 in 1943 and diminished to 11,800 in 1945. This increase in juvenile deliquency in the proportion of 1 to 3 or 4, till 1943 was found in all countries of Europe which had to endure war and occupation, even in Switzerland.

Miscellaneous

The French Society of Phlebology has just been officially organized. It brings together specialists and those who are interested in the study and treatment of diseases of the veins.

From June 24 to 27 the second International Scientific Conference will take place at Aix-les-Bains under the honorary presidency of Professor Besancon and the presidency of Professor Leriche. The principal subject on the agenda is degenerative chronic rheumatism. For full information apply to Dr. Francon, 55 Rue des Mathurins, Paris, 9.

Surgery of the Spleen

A recent meeting of the Surgical and Medical Association of Naples was devoted to surgery of the spleen. Signorelli reported the case of a girl aged 12 years with abdominal syndrome characterized by attacks of painful splenomegaly, rise of temperature, transitory ascites, small liver and positive reaction to the Takata-Ara test. Splenectomy revealed congestive splenomegaly with numerous hemorrhagic intrasplenic foci and annular cirrhosis of the liver. Eight months after the operation the patient was in good health. Signorelli presented also the history of a girl aged 16 with brucellosis of five months' duration; she had undulatory high fever, enlarged spleen and liver, rapid anemization and hemorrhagic manifestations. After two months of ineffective vaccinotherapy, splenectomy was performed and was followed by rapid improvement of the hepatic condition and normal temperature. Microscopic examination of the spleen and biopsy of the liver revealed a congestive hemorrhagic splenitis and an acute hepatitis. The speaker attributed the main responsibility for the clinical aspect to the hepatitis with a vicious circle of chainlike damage (liver-spleen-bone marrow-liver) which may be interrupted only by the removal of the spleen.

Torraca discussed several cases of splenectomy performed for various indications: congestive splenomegaly, Banti's disease, cirrhosis of liver, hemorrhagic purpura, hemolytic icterus, brucellar splenomegaly. The operative course was favorable in all instances.

Late results were satisfactory for months, and in some cases for nine years after the operative intervention. One patient with cirrhosis of liver and splenomegaly died after two years because of recurrence. In 1 patient with Werlhof's disease (thrombopenic purpura) who is still in good health after nine years, the splenectomy had only a transitory effect and the patient had to take vitamin K for a long time.

Perrotti summarized modern concepts of the treatment of splenopathy; he insisted that splenectomy is superior to ligation of the splenic artery.

Insurance Against Occupational Accidents

An agreement was reached between the National Institute of Insurance Against Occupational Accidents and the National Municipal Medical Association, with the following decisions:

1. The assistance given persons who had an accident while working includes first aid and treatment up to the time of recovery, prescriptions and occasional reports required by the institute.

2. The institute will pay as much as 500 lire for the complete cure of each person who had an accident while working or who had an occupational disease.

3. In cases of fractures, the physicians as a rule will limit their care to the application of a temporary apparatus of immobilization and to sending the victim as soon as possible to a nearby hospital or to the Surgical Ambulatorium of the of the institute. A fee of 400 lire will be paid to the physician for the application of any apparatus of immobilization.

BRAZIL

Buenos Aires, March 1, 1948

Surgical Drainage of the Cardiac Lung

To find a surgical treatment for some diseases of the heart which until now have been in the exclusive domain of internal medicine, Drs. Pedro Cossio and I. Perianes of Bueno Aires have performed for almost a year different surgical procedures in animals. These involved more or less risk, and some of them were more physiologic than others. All have been performed to drain the cardiac lung and thereby to alleviate a group of symptoms which burden exceedingly patients with this condition. After having acquired enough experience with animals they carried out the tricuspid valvotomy in men. The technic consists in dissecting the vena jugalaris interna and introducing the valvulotome, which the same authors have described. Afterward the vein is sewed again.

Three patients survived in good condition and continue to live in relatively good health. All three manifested an increase of the vital capacity and of the time of apnea, with diminution of the dyspnea. A fourth patient (a woman) died, probably by paroxysmal auricular fibrillation, from which she had suffered before the valvotomy. She had vomiting and complete aphonia, followed quickly by acute edema of the lung (the patient had mitral stenosis).

It is not possible, of course, to judge the therapeutic value of the operation, although the results are apparently encouraging. The cases are few, and it is known that in cardiology the most unexpected evolutions in the most desperate conditions may occur. Furthermore, the same authors are experimenting on a new way to discharge the cardiac lung by means of an anastomosis of the left vena or arteria pulmonalis inferior with the vena splenica. In this way the blood can avoid the obstacle which would signify a mitral stenosis or an insufficiency of the left ventricle; it returns to the right heart after having passed through a considerable distance. Thus there is no great probability that the right ventricle will get rapidly overcharged as it would, for example, when an anastomosis (vena pulmonalis -azygos- cava superior) had been made.

The Ample Sympathectomy in Primary Hypertension

To the same society Professors Tibrucio Padilla and Pedro Cossio and Drs. Julio A. Berreta and and G.H. Alvarez reported their experiences with splanchnicectomy and postganglionic sympathectomy, ample and bilateral (lumbar or dorsolumbar), which they performed in 34 cases of primary hypertension at the medical clinic of the University of Buenos Aires. The age of the patients varied between 29 and 50 years, only 1 of them was 52, three others were 54 years of age. All except 2 who are not mentioned in the statistics had relatively good renal sufficiency. All showed a good lability of tension; 18 had a cardiopathic condition of different degree. The mortality rate was 9.09 per cent. Although the figure of arterial tension improved immediately after the operation in 50 per cent of patients the percentage decreased rapidly with the course of time, so that after six to twenty-four months only some 17 per cent of the persons operated on were still benefited. The hypertensive condition improved immediately after the operation in nearly all cases, but with time ventricular surcharge and enlargement of the heart reappeared, until the earlier grade was reached or even passed. On the other hand, in some cases the improvement of cardiac insufficiency persisted during a longer period. It is not possible to make an accurate prognosis of the efficiency of the operation, even though the patient's age, the results of the sedative and cold tests and the degree of hypertension are known.

This procedure must be considered as a radical therapeutic step which may be taken in exceptional circumstances, perhaps in rapidly progressing hypertension after all other therapeutic means have failed and in hypertensive cardiopathy (third degree) when the treatment only partly controls the cardiac insufficiency, provided that the patients are under 50 years of age and have good renal sufficiency.

Pan-American Congress of Gastroenterology

The Pan-American Congress of Gastroenterology will be held from March 11 to 17, 1948 in Buenos Aires, under the chairmanship of Professor Carlos Bonorino Udaondo. The main subject will be "Chronic Cholecystitis Without Stones." The different aspects of the theme will be considered by Drs. B.B. Crohn, New York; H.L. Bockus, Philadelphia; C. Bonorino Udaondo, Buenos Aires; Ignacio Chaves, Mexico; Robert Elman, St. Louis; A.C. Broders, Rochester, Minn; Domingo Mosto, Buenos Aires; Pedro A. Barcia, Montevideo, Uruguay; Pedro A Maissa, Buenos Aires; B. Varela Fuentes, Montevideo; A. López Garcia, Buenos Aires; Julio Carrere, Montevideo; Pablo Mirizzi, Cordoba, Argentina; Marcelo Royer, Buenos Aires; A. da Silva Mello, Rio de Janeiro; Alfonso Uribe-Uribe, Bogota, Colombia; Hernán Alessandri, Santiago, Chile; Norberto M. Stapler, Buenos Aires; Félix Amesti, Santiago, Chile; Fortunato Quesada, Lima, Peru; Abraham Ayala González, Mexico, and Adrian J. Bengolea, Buenos Aires. For information address the secretary, Tucuman 1978, Buenos Aires.

Congress of Dermatology

With Professor Pedro L. Baliña, president of the Argentine Association of Dermatology and Syphilology, in the chair, the meeting held in Buenos Aires received great assistance from specialists and several foreign guests, among others Professor José Gay Prieto, president of the Spanish Academy of Dermatology, Madrid, Dr. Arthur Grace (Long Island, N.Y.), Dr. Max Wolf (New York) and well known specialists of Brazil, Chile, Uruguay and Spain. The deliberations were held in three sections: (1) dermatology--the treatment of lupus and other cutaneous tuberculids with the method of Charpy (France), the Besnier-Boeck-Schaumann disease and lupus erythematosus; (2) syphilis-intensive treatment of recent syphilis, and (3) lepra--prophylaxis and treatment with modern methods; their practical application.

From the many subjects treated we may refer here only to the fact that it was the unanimous opinion that there is no tuberculosis causation of lupus erythematosus, which has to be considered as a syndrome in which focal infection, particularly by streptococci, plays an important role and further exterior factors, especially sunlight, participate.

Wiesbaden, April 25, 1948.

Venereal Disease Control Legislation in Germany

Next to the fight against tuberculosis the combating of venereal disease is the most important public health problem in Germany today. This has been recognized by the Allied Control Council, the quadripartite government of Germany, the existence of which is presently the subject of worldwide political discussions.

In a recent draft law, published as an appendix to Control Council Directive 52, the Control Council, "taking into consideration the increasing incidence of venereal disease among the German population and in the interest of health conditions in Germany," adopted a uniform plan and procedure in all the zones of occupation of Germany for the fight against venereal disease among the German population.

Control Council Directive 52

On May 7, 1947, the Allied Control Council, "disturbed by the increased incidence of cases of venereal disease and convinced that one of the causes of this increase lies in the ineffectiveness of the German law at present in force," issued Directive 52, which was designed to combat venereal disease more effectively. This directive imposed on the zone commanders in the four zones of occupation in Germany the duty to examine existing legislation for the control of venereal disease among the German population, whereby particular attention is to be directed to the following points: *(a)* "To determine whether the laws and decrees dealing with the instruction of the people on the control of venereal disease are adequate; *(b)* to achieve uniformity in the detection of cases of venereal disease, the compulsory declaration of such cases to the appropriate authorities and the establishment of isolation wards for treatment of such infections."

To this directive was attached the text of a draft law "Relative to Combating Venereal Disease" and two draft directives, one "On the Enforcement of the Law Relative to Combating Venereal Disease," the other "Establishing Venereologic Diagnostic Centers and Isolation Wards." These constitute the policy of the Allies in this matter and were designed to give guidance to the zone commanders in order to make possible uniform venereal disease control measures throughout the four zones of occupation. The zone commanders were directed to encourage legislation in their zones as nearly in conformity with the draft law and the two draft directives as possible. The following is a short summary of the main provisions contained in this draft legislation on venereal disease, as compared with the German legislation of 1927:

The term venereal disease, as applied in Directive 52, now includes also Nicolas Favre disease (lymphogranuloma venereum and lymphopathia venerea). The draft law provides for the abrogation of the German law of 1927 and its implementations and amendments. Under this draft law it is the responsibility of any person knowingly infected with venereal disease or, by reason of circumstances, suspecting himself to be so infected, *(a)* to have himself examined and treated by a licensed physician until fully cured and *(b)* to refrain from sexual intercourse until permission to resume such intercourse is received from the treating physician.

Any pregnant woman who might transmit syphilis congenitally either because she herself is infected with syphilis or because of known syphilis in the procreator has to take the same measures as referred to under sections *a* and *b*. Sexual intercourse by a person with venereal disease in an infectious stage is under the provisions of the draft law punishable without the former requirement of a request for instituting criminal proceedings. The most important changes brought about by the new draft law are in the field of finding the sources and contacts of the infection. While the old law did not encourage the reporting of one person by another, since it provided that no attention be paid to anonymous reports, the new draft law states that all physicians, on diagnosing a new case of venereal disease, will make every effort to obtain from the patient the maximum useful information for identifying and tracing the alleged source and also sexual contacts that may have been infected by the patient. Such information will be related to the public health authorities without delay. The authorities will then immediately take all necessary steps to induce the alleged source, and all sexual contacts who may have been infected, to submit to a medical examination and, if necessary, to compulsory treatment. In the new draft law the immediate hospitalization is to be recommended by the treating physician in cases (1) where the patient is leading a promiscuous sexual life, whether as a prostitute or not; (2) where the patient is subject of a complaint of infection brought by a member of the occupation forces, or (3) has infected, or is suspect of having infected, a member of the occupation forces.

Subsequent Legislation

On the basis of Control Council Directive 52 and the attached draft law and directives, a law relative to combating venereal disease was passed by the Berlin Kommandatura on Oct. 31, 1947, which is applicable within the city proper. Similarly, on Dec. 11 a law was passed in the Soviet zone of occupation following the pattern of Control Council Directive 52. The differences between these laws and the Control Council draft legislation are only slight and need not be mentioned here. The British Military Government, in its zone, has submitted Control Council Directive 52 and its accompanying draft legislation to the legislative assemblies in the British zone, where the passing of such legislation uniformly and zonewide is under way now. In the American zone of occupation there have been similar debates in the *Laenderrat*. It is to be expected that uniform legislation based on Control Council Directive 52 and its implementation will soon be enacted in both zones.

Miscellaneous

The German Society for Internal Medicine will meet on May 19, 20 and 21, 1948, in Karlsruhe, American zone. The main topics will be the vegetative nervous system, virus diseases and blood pigment. Professor C.M. Haselmann, director of the dematologic clinic of Erlangen University, has been invited by the Cuban government and by the International Leprosy Association to participate as official delegate in the International Congress for Leprosy at Habana. On Dec. 10, 1947, Dr. Gerhard Domagk received in Stockholm the Nobel prize for the discovery of the therapeutic effects of the sulfonamide drugs. Under the Nazi régime he had been forbidden to accept that award.

Medical Motion Pictures

FILM REVIEWS

Anomalies of the Bile Ducts--Blood Vessels and Strictures of the Common Duct, Part I and II. 16 mm., color, silent, 1,200 feet (one reel), showing time forty minutes. Prepared in 1947 by Warren H. Cole, M.D., Chicago. Produced by Mervin LaRue for the American College of Surgeons under a grant from the Johnson & Johnson Research Foundation. Procurable on loan from Ethicon Suture Laboratories, Division of Johnson & Johnson, New Brunswick, N.J.

The anomalies of the bile ducts and blood vessels and strictures of the common duct are treated in two parts in this motion picture. Diagrammatic illustrations and animation are used throughout to identify the normal gallbladder and surrounding adjacent organs. The excision of part of the common duct, thus pulling it into the position normally occupied by the cystic duct, is illustrated by drawings. These drawings show the danger of injury to the common duct during cholecystectomy when an unusually large Hartmann's pouch densely adherent to the common duct is encountered. Injury of the duct if hemorrhage is not controlled correctly when ligating the vessels is demonstrated; an accessory bile duct which is severed and not ligated may result in a stricture. Other causes of stricture of the common duct, not related to trauma, are described as diffuse sclerosing pancreatitis, abscess about the duct, ulceration of the wall by stones and suppurative cholangitis. Observation of certain precautions given in the film will be of great value in reducing the incidence of stricture of the common duct. Conditions such as injury or obstruction to the common duct causing a biliary fistula or jaundice developing postoperatively are described clearly.

The various types of strictures such as local stricture, stricture of the distal end, stricture of the proximal end and absence of the entire duct are clearly presented in drawings. However, in most cases the distal end of the common duct is present but is difficult to find because of its position under the duodenum and in the head of the pancreas. Although the original trauma may be limited to a small portion of the duct, the entire duct can be involved by a process known as obliterative cholangitis. In the repair of local strictures metal tubes are used for support at the anastomotic line for at least three months following repair; however, most surgeons insert a T tube with one arm extending beyond the suture line. Procedure for anastomosis of the common duct to the duodenum and the use of the Roux y-arm of jejunum with the use of metal tubes for a support or the use of the rubber catheter are clearly demonstrated. The incidence of congenital atresias are mentioned, namely: hepatic duct patent, atresia of extrahepatic ducts (7 per cent), atresia of hepatic duct, cystic duct and common duct normal (11 per cent), hepatic and proximal portion of common duct patent (14 per cent) and atresia of all extrahepatic ducts (70 per cent).

The film is brought to a conclusion by summarizing the following facts which were emphasized throughout: During operation avoid trauma, carelessness and haste; be on the alert for anomalies, and have thorough knowledge of normal anatomy in the region of the gallbladder. Well prepared, still drawings constitute the majority of illustrations in this picture. However, various camera methods were used to give the illusion of motion. If sound slide film projectors were more readily available in medical schools and hospitals, the production of a film strip instead of a motion picture might have been considered. This is an excellent educational technical film, since it points out the anatomic relationships of the biliary passages. It can be recommended for showing to groups of general surgeons, interns and possibly senior medical students.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARD OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, May 29, page 487.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Parts I & II Various centers, Sept. 13-15. Final date for filing application is Aug. 13. Exec. Sec., Mr. Everett S. Elwood, 225 South 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: Written. Various Centers, July 16. Oral, Philadelphia, Oct. 10, Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

American Board of Dermatology & Syphilology: Oral. Groups A & B. Ann Arbor, Oct. 21-23. Final date for filing application is Aug. 2, 1949. Written. Ann Arbor. Sept. 9, Sec., Dr. G. M. Lewis. 66 E. 66th St., New York 21.

American Board of Neurological Surgery: Oral. Chicago. June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German. 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology: Part I. Various Centers, Feb. 4, 1949. Final date for filing Application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 1.

American Board of Ophthalmology: Oral. Chicago, Oct. 6. Written. Various centers, Jan. 1949. Final date for filing application is July 1, 1949. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: Part II. Chicago. January 1949. Final date for filing application is August 15. Sec., Dr. Francis M. McKeever, 1136 W. 6th St. Los Angles 14.

American Board of Otolaryngology: Oral. Chicago, June 15-19. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Chicago, Oct. 8-9. Final date for filing application is Oct. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: Chicago, June 25-27. Seattle, Sept 10 12. Atlantic City, Nov. 17-19. Written. July 30. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines, Iowa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the hometown of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis.

American Board of Psychiatry and Neurology: Oral. All Groups, San Francisco, October. Final date for filing application is July 15. Sec., Dr. F. J. Braceland, 102-110 Second Sve., S. W., Rochester, Minn.

American Board of Radiology: Nov. Final date for filing application is Sept. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S. W. Rochester, Minn.

American Board of Surgery: Written. Part I. Oct. Final date for filing application is July 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Chicago, Feb. 12-16, 1949. Final date for filing application is Sept. 1. Sec., Dr. Harry Culver. Route #13, Sunnyside Rd., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Bull. of U.S. Army Med. Dept., Washington, D.C.

8:81-164 (Feb.) 1948

Anopheles Gambiae Problem in Brazil and West Africa, 1941-1944. E. Farrell.—p. 110.
Coccidioidal Infection. F. W. McLaughlin.—p. 124.
Studies on Schistosomiasis: II. Summary of Further Studies on Methods of Recovering Eggs of S. Japonicum from Stools. G. W. Hunter 3d, E. P. Hodges, W. G. Jahnes and others.—p. 128.
*Tuberculous Pleurisy with Effusion. I. G. Karron and R. K. Purves.—p. 131.
Clinical Aspects of Protein Metabolism. Co. Tui.—p. 136.
Clinical Importance of Rh Factor. P. Levine.—p. 139.
Diagnosis and Treatment of Essential Hypertension. J. Redish.—p. 146.
Surgery of Hypertension. B. S. Ray.—p. 151.

Tuberculous Pleurisy with Effusion.—Karron and Purves present observations on 215 cases of tuberculous pleurisy with effusion. Cases of pleurisy secondary to pneumothorax are not included. This is a select group, since it consists only of male American soldiers hospitalized at one of the Army tuberculosis centers. The great majority of these soldiers were transferred from other Army hospitals. The past histories revealed that 12 per cent of the patients had close contact with an open case of tuberculosis in civil life. In addition, 11 per cent were liberated prisoners of war, most of whom were exposed to cases of tuberculosis, giving a combined contact history in 23 per cent. Commenting on the pathogenesis, the authors say that it has been suggested that pleural effusions result from the rupture of a caseous tuberculous hilar node into the pleural cavity, either directly or through a small zone of intervening lung that has been consolidated by periadenitis. In this group, however, hilar adenopathy was present in less than 1 per cent of the cases. Parenchymal disease was present in 42 per cent of this group of 215 patients. Dissemination occurred in 16 per cent during the six to twelve month period of observation.

*Streptomycin in Genitourinary Infections. C. G. Bandler, P. R. Roen and V. J. Mulaire.—p. 96.
Modification of Brown-Buerger Cystoscope. C. A. Fort.—p. 111.

Hypertension in Unilateral Renal Disease.—Sabin shows that there is experimental evidence which indicates that interference with the circulation of one or both kidneys may result in the liberation of a pressor substance into the blood stream with resulting hypertension. This pressor substance has not been demonstrated in the peripheral circulation of human subjects or experimental animals with hypertension. Sabin analyzed 100 cases from the literature in which nephrectomy was performed in unilateral renal disease associated with hypertension and has added one of his own. In 51 of these, the blood pressure returned to normal, although 21 had been followed less than a year since the time of operation. Twenty three showed a reduction in blood pressure but not to normal levels, while in 26 no improvement was obtained. The commonest pathologic condition in these cases was chronic pyelonephritis, the kidneys frequently showing atrophy. The cases of hypertension which may be cured by nephrectomy are comparatively rare. Great care should be exercised in evaluating the functional capacity of both kidneys before operation is contemplated. Compensatory hypertrophy of the healthy kidney is a good indication of a successful outcome. Generally speaking, the younger the patient and the shorter the duration of the hypertension, the better the results.

Cancer of Male Breast After Treatment with Estrogen.—Abramson and Warshawsky report the case of a man, aged 51, in whom diagnosis of carcinoma of the prostate with osseous metastases was made. The case was considered terminal and measures for the relief of pain were recommended. He was placed on 1 mg. of diethylstilbestrol daily with much relief of pain and improvement in general well-being. The patient refused to consent to orchiectomy and was discharged March 2, 1944 with the advice that he continue to take diethylstilbestrol, 1 mg. daily, indefinitely. Several months later swelling was noticeable in the mammary region. Subsequently the enlargement of the breast increased. At necropsy the breasts and axillary tissues showed neoplastic growths. Microscopic studies revealed that histologically the tumor of the prostate as well as that of the breast was primary. The metastases in both axillary nodes came from the tumor of the breast. The authors think that there is strong evidence of a causal relationship between the hormonal therapy and the development of cancer of the breast. The total amount of diethylstilbestrol used was 1,097 mg. This treatment had extended over a period of four hundred and eighty-nine days. Awareness of the likelihood of the development of cancer of the breast in the male receiving estrogenic therapy for carcinoma of the prostate is important. The changes in the breast incident to such therapy should be carefully observed.

Streptomycin in Genitourinary Infections.—Bandler and his associates analyze results obtained in 15 patients with urologic infections in whom streptomycin was used. There have been cases in which streptomycin proved lifesaving after other measures failed. The urine may become sterilized, provided the offending organisms are susceptible to streptomycin. Failure to correct obstructive factors is responsible for the recurrence of infection and may be a factor in the development of bacterial resistance to streptomycin. In the presence of a calculus or of a nephrostomy tube, renal infection may be eliminated temporarily by streptomycin, but unless the obstruction is removed there will soon be a recurrence of the same organisms. In vitro tests of susceptibility of an organism to streptomycin cannot always be relied on to determine its effect in the patient. The immunologic response and resistance of the patient may change the clinical response to the antibiotic. There has been clinical improvement despite the fact that bacteria were still present in urine cultures, indicating that streptomycin may have been effective in altering the pathogenicity of the organisms. In nonspecific prostatitis it is possible to free the prostatic secretions of pathogenic bacteria for brief periods; however, streptomycin does not change the course of this disease entity. The streptomycin presently available has neurotoxic properties. In this series of 15 cases there were 2 cases of toxic labyrinthitis and 1 case of involvement of the left recurrent laryngeal nerve. In a fourth case there was mild and transitory involvement of the facial nerve. In view of the potential toxicity of streptomycin, its prophylactic use in urologic surgery should not be indiscriminate. Since this report was written, the authors have treated many more patients with streptomycin, confirming the impressions and conclusions already stated.

Clinical Aspects of Sarcoidosis. C. Cameron. -p. 88.
*Observations on Sarcoidosis. C. Hoyle. -p. 92.

Observations on Sarcoidosis.--Hoyle says that among 135 patients whose clinical features gave some reasons for considering sarcoidosis, the diagnosis could be regarded as endorsed in 16 only by histologic support. Another 14, though probable examples, were unconfirmed, and in 32 others alternative diagnoses seemed just as likely. Of the remaining 73 patients, 53 had chronic miliary tuberculosis. The lungs are among the organs most commonly affected by sarcoidosis. The characteristic form of the disease is a combination of lymph node enlargement, cutaneous lesions and uveoparotitis. In this triad the intrathoracic lymphatic system takes a prominent share, for enlargement of the bronchopulmonary and mediastinal lymph nodes is an early and persistent feature. The miliary type of sarcoidosis shows nothing distinctive of its origin. The shadows conform in size, distribution, density and numbers to the picture of miliary tuberculosis. Both miliary and focal varieties may eventually resemble diffuse fibrotic tuberculosis when the lesions have contracted and scarred. Reviewing observations on tuberculin sensitivity in sarcoidosis, the author shows that two reflections are suggested: that patients with sarcoidosis and a negative Mantoux may not previously have had a positive reaction, and that the disease could still be tuberculous in spite of a persistently negative reaction, belonging then to the deceptive class where tuberculin sensitivity does not develop or is readily suppressed. The author stresses that however the disease is regarded, whether from its clinical appearance and course, its radiology, its morbid histology or its intractability to transmission--the similarity to known examples of tuberculosis is a constantly recurring feature. Although this similarity is no proof of identity, it is so close that separation has become meaningless.

Monatsschrift für Psychiatrie und Neurologie, Basel

Heredity and Pathohistology of Spastic Spinal Paralysis. I. Farago.—p. 161.
Acute Ependymitis of Lateral Ventricles with Intracranial Increase in Pressure and Hyperkinetic Psychosis. G. Pamboukis and G. Anastasopoulos.—p. 193.
*Diphtheric Polyneuritis in Adults. Z. Böszörmenyi.—p. 209.

Diphtheric Polyneuritis in Adults.—Böszörmenyi reviews observations on 14 adults, varying in age between 20 and 50 years, in whom there developed paralysis of the cranial nerves from one to five weeks after onset of pharyngeal diphtheria. Accommodation and innervation of the soft palate were most frequently involved. From six to twelve weeks after the onset of diphtheria paresthesias appeared in the extremities, and these were followed by paralytic symptoms in the extremities and sometimes of the trunk. The reflexes were often reduced or abolished. The albumin content of the cerebrospinal fluid was frequently increased. The therapeutic measures included physical therapy, autohemotherapy, administration of vitamin B_1, strychnine and liver extracts. In some cases drainage of the cerebrospinal fluid was employed. Most patients recovered within six months. In a married couple the disease took a grave and prolonged course; in one of them a picture resembling Landry's polyradiculitis developed; in the other symptoms of myelitis. In these cases the possibility of superinfection by a virus is considered.

*Pathogenesis and Therapy of Acute Anterior Poliomyelitis. M. Acqua. -p. 461.

Pathogenesis and Therapy of Acute Anterior Poliomyelitis.—Acqua states that there is a relation between poliomyelitis and both gastrointestinal infection and cutaneous allergy. The author carried on research in three different groups of patients. Patients in the first and second groups were seen by the author early in the period of paralysis and during the regression of paralysis. Those in the first group had gastrointestinal disorders in the prodromal period which were absent in those in the second group. Vaccines were prepared with killed cultures of intestinal bacteria and intradermally administered to patients in the first group. Negative results were obtained from vaccines of coli bacillus, whereas vaccines from enterococcus, pyocyaneus and proteus either alone or in association caused an allergic cutaneous reaction and regression of paralysis, which effects were moderate for single vaccines and severe for associated vaccines. Patients in the second group had autovaccines which were prepared from the patients' own nasopharyngeal secretions. Autovaccines failed. However, when they were given in association with vaccines of intestinal bacteria the cutaneous reaction was as strong as that which had been observed in patients in the first group and the regression of paralysis equally well defined. The third group of patients was large. It included patients with paralytic sequels of from ten to fifteen years' duration. Reaction of the skin was definite in these patients, and the return and progressive improvement of muscular function were surprising.

*Employment of Women During Pregnancy. H. Heidler. -p. 805.
Suggestions for Combat of Epidemic Poliomyelitis. F. Kress. -p. 808.

Employment of Women During Pregnancy.--Heidler believes that housework is generally not too much exertion for pregnant women. Shopwork at home does not seem to exert such unfavorable influences as does work in factories, particularly when it involves work on machines. Statistics indicate that prolonged standing is especially harmful. Varicose veins are much more frequent in those whose occupation involves prolonged standing. It is probable that certain toxic substances used in some industries may increase the incidence of premature births or stillbirths. Among such toxic substances the author mentions lead, which is used in toy and ceramic factories and in production of artificial flowers, and mercury, which is used in mirror factories and in the hat and fur industry. Obstetric and puerperal complications are greatly increased among women who work in the textile industry, particularly in those who work while standing. Industrial work also involves disadvantages for lactating women.

Book Notices

Modern Treatment of Peptic Ulcer. By Asher Winkelstein. Cloth. Price, $4. Pp. 205. Oxford University Press, 114 Fifth Ave., New York 11, 1948.

This handy volume presents in detail the extensive experience of the author and his associates at the Mount Sinai Hospital in New York in the treatment of peptic ulcer. The most useful section and one which all internists will welcome describes fully the author's method of treating peptic ulcers by means of a continuous drip of nutritive and alkalinizing solutions into the stomach. The theroetic background for this treatment is ably presented. Present recognition of the fact that most patients with ulcer secrete large volumes of highly acid gastric juice in the empty stomach at night is partly due to the author's pioneer researches in this field and the logic of neutralizing this corrosive fluid by the continuous intragastric drip is appealing. It represents an important extension to the basic concept of Sippy's method. The chapters dealing with the pathologic physiology of the stomach in ulcer and on the pathogenesis of the disease are less complete and valuable. Probably not many will agree with the author's contention that his associates should be largely credited with the present interest in vagotomy. Partial division of the vagus supply to the stomach such as is practiced and described from this clinic and in the older literature has elsewhere been found not to be of much value. The book, however, does not purport to be a surgical treatise and this should not detract from its manifest usefulness as a guide in medical therapy.

Jonathan Hutchinson: Life and Letters. By Herbert Hutchinson. With a foreword by J. Johnston Abraham. Cloth. Price, 12s. 6d. Pp. 257, with illustrations. William Heinemann, Medical Books, Ltd., 99 Great Russell St., London W.C.1 1946.

When Jonathan Hutchinson died his medical career was evaluated in obituaries by such distinguished persons as Sir George Newman and Sir Thomas Barlow. Now on the basis of great numbers of letters written to his wife and friends Herbert Hutchinson has prepared a biography which tells the story of this famous Quaker who was stirred by Darwinism and who contributed vastly to medicine and science. His was a great mind a d his biography takes its place among the distinguished works of its type in the field of science.

A History of Medicine. By Arturo Castiglioni, M.D., Research Associate in the History of Medicine at Yale University, New Haven, Conn. Translated from the Italian and edited by E. B. Krumbhaar, M.D., Ph.D. Second edition. Cloth. Price, $12.50. Pp. 1253, with 504 illustrations. Alfred A. Knopf, 501 Madison Ave., New York 22, 1947.

The second edition of this important philosophic consideration of the history of medicine is much enlarged over the previous edition. Its approach to the problems of medicine is quite different from Garrison's book. Professor Castiglioni views medicine with a broad outlook in relationship to its position in society. He considers trends and the reasons for their development. In this history various discoveries are considered in proportion to the whole field of medicine and civilization. The history by Castiglioni can be read and is far more than a reference work. It deserves a place in the library of every physician interested in the cultural aspects of medicine.

De Primaire Atypische Pneumonieen Van Onbekende Oorsprong. Door Dr. Th. van Erp. (Primary Atypical Pneumonias of Unknown Origin.) Paper. Price, 6 guilders. Pp. 124, with illustrations. E. J. Brill, Ltd., Leiden, Holland, 1947.

This is an excellent monograph composed essentially of a review of the literature on the pneumonias of supposed virus origin, illustrated by appropriate case reports selected from the records of 130 patients studied in a hospital. The patients were chiefly workers in the petroleum industry in Curacao, Netherlands West Indies, and the occurrence of the disease in several hundred persons there after 1943 appeared to be part of the worldwide pandemic of the infection at that time. The subject is dealt with under the usual headings of clinical aspects, complications, roentgenology, clinical pathology, etiology, diagnosis, prognosis and therapy. No controversial points are raised, since the author comfirms almost all the previously reported observations. The bibliography contains one hundred and eighty-two references, and credit is carefully given where credit is due.

Betrachtungen zur Individualpsychologie. Von Dr. Siegfried Novotny. Paper. Price, $1.20. Pp. 63. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2, 1947.

Dr. Novotny, a senior psychiatrist in the large municipal mental hospital of Vienna, "Am Steinhof," wrote this brief outline of Adlerian theory and therapy in a philosophic vein. For instance, he refers to Kant to explain Adler's concept of conscious versus unconscious. The book centers around the importance of social interest and its limitation through inferiority feelings, which are always self deceptions. The author goes to great length in explaining the mechanism, causes and effects of inferiority feelings. He describes the the three life tasks of work, marriage and social relationships. It is interesting to note that he substitutes Adler's term " style of life" with " Primaeres Leitbild" (primary guiding concept). He gives a good description of the differences between psychoanalysis and individual psychology. The first tries to explain psychic life as a system of conflicting energies, while the latter tries hard to avoid mechanistic concepts; in contrast to psychoanalysis, which is causalistically oriented in describing the effects of various antagonistic instinctual desires, individual psychology sees each person as a unit who can be understood only by his goals.

The importance of courage and the pathologic significance of discouragement are extensively discussed. Neurosis is described as an illusion to conceal anticipated or actual defeat. It serves (1) as a retreat, and for the creation of distance from social living; (2) as illusory satisfaction of the desire for significance; (3) to influence the environment, and (4) to conceal these three tendencies from the patient himself. If the body responds to such tendencies, the ensuing psychosomatic symptoms serve these neurotic purposes. The goal of psychotherapy is to make the patient aware of his goals and of his errors in his self evaluation and to induce him to change his attitudes and concepts. The primary means to this end is encouragement. The author advises letting the patient talk freely in order to find out, first, what the patient really wants. The faulty concepts which have been unknown to the patient must be brought into consciousness, and the more adequate concepts must be so well established that they can sink again into unconsciousness. This means cure.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. REMOVAL OF WARTS

To the Editor:—Kindly send me literature or information on the use of liquid oxygen in the removal of moles and warts.

G. L. Harker, M.D., Nogales, Ark.

ANSWER.—An article by Irvine and Turnacliff (*Arch. Dermat. & Syph.* **19**:270 [Feb.] 1929) has a historical review of the subject, a report of results obtained in various types of lesions and a full discussion by a number of dermatologists. More recently, in June 1947, Kyle and Welsh of Cincinnati read a paper on the subject at the annual meeting of the American Medical Association in Atlantic City, N. J. This has not yet been published but will appear soon in the *Archives of Dermatology and Syphilology*. Both papers report satisfactory results from the use of liquid oxygen on superficial lesions such as warts and keratoses, and both stress the ease with which it is applied. Liquid oxygen, however, is available in relatively few communities.

ULCERATION OF MOUTH

To the Editor:—A white woman aged 35, married, a doctor's assistant, has had ulcers in her mouth off and on for two years. Ulcers vary from pinpoint to matchhead in size, are round with grayish white membrane and always start as a small herpes. Usually eight to ten are present at one time, principally on the inner surfaces of the lips, although a few appear on the buccal surface of the cheeks. They are extremely painful. During the past two years there was one remission of two months. Gold and silver dental work was performed two years preceding ulcerations in the mouth. She has occasional attacks of hay fever in spring, summer and autumn, but attacks are never severe. In 1941 she had a positive reaction to a skin test for undulant fever. At that time she was running an afternoon temperature of 102 to 103 F. Complete rest in bed for six weeks was prescribed and three ten-day courses of a sulfonamide drug with two-day free intervals were given. Injections were also given at that time, but she has no idea what they were. Undulant fever has not bothered her much since, except that she believes she occasionally runs a slight afternoon temperature. She had a mild attack of urticaria in 1934 and was told that this was caused by eggs and pork. Menses, which started at the age of 13, were seldom regular and occasionally absent for six months at a time; flow was scanty and of only two days' duration. In 1939 the fundus of the uterus and two tumors, or cysts, from one ovary were removed. She had regular scanty menstruation for two years following surgical intervention and has not menstruated since. She has received extensive vitamin therapy and penicillin. The Wassermann test is negative. Ulcers clear up in seven to ten days with or without treatment, only to recur in two or three weeks.

I first saw her in May 1947. The white blood cell count was 11,800, red blood cell count 4,370,000 and hemoglobin 86 per cent. Urinalysis was normal; the basal metabolic rate was plus 2 per cent; gastric analysis revealed free hydrochloric acid 31 cc. and total acidity 51 cc. Protein scratch tests elicited slight reaction to a few foods, but her diet was revised without beneficial effect. Administration of "pyribenzamine hydrochloride" (tripelannamine hydrochloride) 50 mg. gave no relief.

The patient states that ulcerations are usually preceded by a swollen axillary lymph node, sore breasts, a feeling of exhaustion and drowsiness. Suggestions for diagnosis and treatment are requested.

M.D., Missouri.

ANSWER.—A woman aged 35 has had herpes leading to canker sores on her lips and in her mouth for two years, since age 33. The lesions last for seven to ten days at a time and then leave her free for two or three weeks, only to recur again. Once she was free for as long as two months.

Meanwhile she has had mild hay fever and, more important, she has had for six years, since 29 years of age, attacks of fever with temperature up to 103 F. keeping her in bed for six weeks at a time, with sulfonamide drugs administered in courses. The history says nothing concerning the relation between the aphthous stomatitis (canker sores) and the fever or between the stomatitis and the drugs received, and study of the time relations might be helpful.

Undulant fever (brucellosis) has been suspected, especially because skin tests with the Brucella antigen were positive. The patient does not have persistent leukocytosis, although there is evidence of slight anemia. Other chronic infections must be considered. Malaria, rheumatic fever, pyogenic infections, cholecystitis or even endocarditis may cause such symptoms and may be overlooked quite easily.

Herpes and aphthous stomatitis can depend on a local virus infection, but if so they pass off promptly and would hardly recur for two years. Similar lesions can depend on an allergy to foods, but the cases are very rare. In this instance there is no evidence of sensitivity to food either by skin tests or by dietary changes.

Finally, herpes and aphthous stomatitis often occur as complications of acute and chronic infections, and it is possible that the basic lesion here is the infection. Brucellosis alone could cause this clinical picture. On the other hand, allergy to drugs occurs when least expected, and the sulfonamide compounds are particularly prone to produce reactions of this sort.

Treatment is difficult, and when allergy to drugs is suspected the problem becomes even more difficult. Antibiotic agents are not of much value against brucellosis. Penicillin and streptomycin have been tried without success. The sulfonamide drugs have helped in some cases when first used, but later the effect has worn off. General supportive measures are essential; if the diagnosis of brucellosis can be supported, one can consider more active forms of treatment such as vaccines and extracts made from the Brucella organism and its cultures. Unfortunately, treatment of this kind is new and no one knows very much about it. This particular patient will need much further study before an accurate diagnosis can be made and proper therapy applied.

"DICUMAROL" AND PROTHROMBIN

To the Editor:—After I had abnormal bleeding in patients treated with "dicumarol" who apparently had fairly good prothrombin levels (40 per cent of normal), I investigated the laboratory methods used and the method of calculation of percentage of prothrombin. I found two entirely different methods of calculation, neither of which is correlated with the other. The method most widely used is to divide the normal time in seconds by the abnormal. This figure is reported in percentage of normal. This method is described in several textbooks and is the method advocated by the manufacturers of thromboplastin. The arithmetic used in this method is in error and no correlation exists between this method and that advocated by Allen and associates, which is: dilute normal plasma to 10 per cent, 20 per cent, 30 per cent, etc., and compare this time with the unknown.

At the Good Samaritan Hospital in Cincinnati, we calculated percentage according to both technics with the startling results:

Percentage as Calculated by Allen's Method	Time in Seconds	Method in General Use (n/u × 100)
10%	60 to 70	25%
20%	30 to 45	50%
30%	20 to 22	75%
40%	17 to 20	80%

No correlation between the two sets of figures occurs. If Allen's method of prescribing "dicumarol" is used with the alternate method of reporting prothrombin percentage quite disastrous results may be expected. I found this to be true on interrogating the local physicians and members of hospital staffs. Laboratories almost universally were reporting in the percentage of normal (n/u x 100) and physicians just as universally were prescribing according to Allen's technic, with some unhappy results.

I have found almost every one, both in clinical practice and in the laboratory, unaware of this discrepancy until it was pointed out to them. With a drug as powerful as "dicumarol" there is no place for uncertainty or inaccuracy in the laboratory technic, the calculations or the method of reporting. It might be wise to discard percentage reports entirely and to report in seconds, with the normal also given in seconds. If percentage reports are to be retained, the method for determining percentage should be standardized.

D. C. Rivers, M.D., Cincinnati.

ANSWER.—A safe and accurate way to express prothrombin activity is as per cent of normal. This value can be calculated fairly accurately by the equation: $C = \frac{k}{\text{p.t.} - a}$ (c = concentration or prothrombin activity as per cent of normal; p.t. = prothrombin time; k and a are constants which have a value of 303 and 8.7 respectively, provided 12 seconds is obtained for normal plasma). To calculate prothrombin per cent by dividing the normal by the abnormal prothrombin time is entirely erroneous.

The present confusion will not be remedied until a standard procedure is adopted. The most reliable course would be to follow the directions as outlined by Quick (*Am. J. Clin. Path.* **15**:560 [Dec.] 1945). Various modifications, particularly the bedside method, the diluted plasma method and other procedures using thromboplastins of dubious activity had best be entirely discarded. Rabbit brain dehydrated with acetone furnishes the most satisfactory source of thromboplastin, because if properly prepared it has a high and consistent activity and deteriorates slowly. If a prothrombin time of more than 13 seconds is obtained on normal plasma, it is best that a prothrombin time be also run on 50 per cent and 20 per cent plasma (i. e. normal plasma diluted with one and four parts of isotonic sodium chloride solution, respectively) and reported with the unknown. For effective "dicumarol" action the prothrombin time should be reduced to the 20 per cent level, i. e., to the prothrombin time of 20 per cent plasma.

AMERICAN MEDICINE AND THE SPIRIT OF ITS PROGRESS

R. L. SENSENICH, M. D.
South Bend, Ind.

"It is apparent that the United States under its voluntary system of medical care has made greater progress in the application of medical and sanitary science than any other country. This progress is now reflected in low mortality and morbidity rates of infectious diseases and in increased life expectancy. There is every reason to believe that these trends will continue unabated under our present system of medical care.'

This paragraph is taken from the conclusions of the report from a study by the Brookings Institution made at the request of Senator H. Alexander Smith, Chairman of the Subcommittee on Labor and Public Welfare.

The conclusion from an objective and unbiased authority commands respect. Since medicine attained this high position in America, let us consider how we have maintained this superior service. I shall endeavor briefly to set forth my analysis of the factors that have made this progress possible. In order that our discussion may be more understandable, let us first define medicine in terms of research and use of discoveries and methods from many scientific fields and in terms of the service it renders to the individual patient.

Within human consciousness, man is the most complex product of nature. Medicine is based on the study of man and requires scientific knowledge of the processes on which life depends. The changes that occur in microscopic cells, cellular reproduction and embryologic development, growth, nutrition, metabolism and, finally, the processes of ageing comprise the universal sequence in the progress of living.

Illness may result from inherited deficiencies, failures of normal body functions or physiologic accidents. These, too, are necessary fields of study in acquiring medical knowledge of man. But man is associated with everything in nature, so that disease may arise from any contacts or deficiences in man's environment. The chemical and moisture content of air, sunshine and temperature may be favorable or unfavorable to health. The recognition of viruses, microbes and parasites that cause disease and necessary protection from them are also a part of medicine. The manner of conveyance of disease by contact with sufferers from the disease or animal carriers is of established importance.

In the treatment of disease, medicine must be familiar with normal physiologic function and methods of restoration from disturbance of such function to normal. As agents in treatment, medicine takes from botany various plant products, from chemistry the substances needed to supply deficiencies and to destroy bacteria. From the blood come protective factors and serums. From electrical energy, special currents are used for various purposes, and radioactive products are employed for the destruction of diseased tissues. Last, but perhaps foremost, is discussion of the tremendous area of the emotional life of man, varying from the normal psychology of life to the medical problems of the abnormal. Again medical science must explore a great area of human development and social experience. The normal emotional development from infancy to maturity, the interests, incentives and happiness of man and the problems of immaturity, maladjustment, frustration or the extremes of crime and psychosis are vital medical interests.

This somewhat lengthy inventory is an indication of the considerations necessary in an effort to appraise medicine, its dimensions and progress. High standards of medical education and careful selection of students are important to the progress of a professional service of such broad scientific basis.

MEDICAL EDUCATION

A long and arduous course of training is necessary to equip physicians to provide a high quality of medical service. The formal educational program of students of medicine, therefore, requires a minimum of seven years. Special training requires several additional years. But, more than this, progress in medicine is so rapid that the effective physician must continue to be a student and research

---

Address of the President of the American Medical Association delivered before the Ninety-Seventh Annual Session at Chicago, June 22, 1948.

observer throughout his entire professional career. His value to his patients will depend on this scientific qualification, to which must be added the indescribable humanity, sympathetic interest, clear judgment and inspired responsibility which produce the best service to the sufferer. Therefore, medical students are carefully selected, and the course in preparation for medicine is longer than that required in most other professional fields.

As a result of this scientific preparation and organization of effort, medical science in the United States has attained remarkable results and medicine continues to progress in advance of social progress. Men live in the United States in good health to greater average age than ever before in the history of any nation. The general levels of health and added longevity accomplished by health education, medical research and development and the use of new methods in prevention and treatment of disease mark scientific advances in medicine unequalled in any comparable division of science.

The benefits of those advances have been effective in the reduction of the incidence of disease, shortening of the periods of illness and lengthening of life in all income groups. This superior comprehensive service, despite general economic inflation, has been delivered to the individual patient with a minimum increase in physicians' fees despite vast increases in cost of various commodities and labor. These increased costs of materials used by physicians and maintenance expense have reflected on the physician as well as the patient. Hospital costs to the patient have necessarily reflected the increased costs of food, supplies, labor and materials in the same proportion as they have reflected on the civilian public.

INADVISABILITY OF GOVERNMENTAL PLANS

The fact that scientific advances in medicine have progressed much more rapidly and to a point far in advance of social and economic thinking is evident in proposed governmental plans for changing our system of medical care. These plans are seldom concerned with better or more effective mechanisms to advance the quality of medical care. They provide little or nothing new to advance the levels of health or happiness. Finally, a consideration of the operation of plans in effect in other nations reveals no evidence to recommend them for use in the United States, where already higher levels of health care are available to more people than anywhere else in the world.

The economic levels, or the standards of living, in the United States are much higher than in other countries. The areas in this country in which present medical standards are economically impossible are minimal in number as compared with the total nation. Education in health and some improvement of medical facilities will require only local effort with possibly some assistance from national resources, but not governmental interference, with the inevitable deterioration of the medical service of the whole nation. If a local area is economically able to correct conditions, this effort should be encouraged. If outside aid is necessary, it may come from federal tax funds derived from general taxes applied to all income groups. Federal aid for medical care should not be taken from funds derived from taxes improperly called insurance and applied only to lower income groups of employees. One wonders at the shortsightedness of labor leaders who advocate legislation that depreciates the civic status of those they represent.

Better social thinking could be directed to better education in healthful living; encouragement to cooperation between labor and employers in industrial health efforts; better housing; education in nutrition; encouragement in wholesome recreation; incentive or assistance through local autonomies in the building of health facilities such as hospitals; stimulation of interest and pride in health activities, and encouragement to voluntary insurance plans against costs of illness.

Especially constructive and much needed now is planning of happier years for people in the older age groups. Existing economic practice excludes men from employment after age 65 and places in idleness and unhappiness many whose experience and capacity would still be useful. With average ages now approximately 67 or 68 years, many men and women now 65 years old will still be living in 1970. Medical progress is constantly extending the life expectancy of human beings. According to recent statistical studies, in 1900 there were about 3,000,000 persons in the United States aged 65 or over. In 1940, there were 9,000,000 aged 65 or over. Estimates suggest that there will be 14,000,000 aged 65 or over by 1960 and 21,500,000 in that age group by the year 2,000.

The three highest ranking causes of death, heart disease, cancer and hardening of the arteries with cerebral hemorrhage, are diseases of the older ages. Nephritis, diabetes and general arteriosclerosis are also in this older age group. More research is now being directed to these degenerative diseases of the older age group. Much may be done in prevention of these diseases by educational programs, good living habits and recreation.

Medicine is constantly exploring new fields pertaining to body function, health and disease. As a result, scientific theory continues to advance. Many physicians in all parts of the country apply themselves to these scientific leads, and discoveries of great importance to the extension of healthy living may be developed at any time. Scientific research is the accomplishment of unusual mental capacity and training. Experience has shown that it does not flourish in a political atmosphere. If social thinking is to follow a proper course of evaluation of methods, it should not deal in the abstract as if groups were the ultimate units of interest and that service is, therefore, best directed by government.

The individual is important in modern civilization. Each human being is a more complex structure than any social system to which he belongs. As far as medical service is concerned, the best medical care is concerned with prolonging one life for one individual.

Physical sickness is always accompanied by mental and spiritual problems. Medical service must be directed to the whole man. The completeness of his recovery may depend on his mental appraisal of himself, on new outlook, renewed confidence and possibly adjustment to conditions which the individual is powerless to correct. The survival of a normal personality, even with an impared body, is vital to the health of man.

The individual human being may occupy a position in the social structure in which his particular tasks and kind of employment in industry are predetermined by others and are not within his control. The maintenance of a proper respect for the personal identity of of that patient in his efforts to recover physical and mental health is recognized as supreme by medical science. In this contact, the patient must have confidence in his physician, and the physician must be interested in and fully cognizant of his responsibility to the patient. Political medicine lacks the spirit necessary for that service.

Individual medical service goes beyond the treatment of disease. Preventive medicine in the field of general protective measures, water and food sources, vaccination and quarantine are of necessity carried on by governmental organizations. But each person is sick or unhappy in his own way. Preventive medicine, in addition to the general plan, must be directed to the individual patient and his needs for special protection. Again, this requires the individual physician.

Physicians are rapidly expanding preventive service as patients request routine examinations of sufficient detail to determine general health and advice as to future health measures and general plan of living.

Another service of medicine, as yet without distinctive name, has to do with the potential capacities and fitness of an individual for certain fields of endeavor. Many men consult their physicians before undertaking any new enterprise that will require physical or mental or possible emotional change from past patterns. This is a most important personal service. Social thinking should recognize the importance of this service, which will no doubt increase.

The physician continues to extend greater service to the individual. Every important advance in health planning, governmental and civilian, and the superior quality of medical service provided have been fostered by and supported by physicians. Without that support, not one could function. Great harm may be done by overemphasis on the value and the importance of the assumption of authority by the social organization. The value of a social system lies in its provision of opportunity and certain social values to the individual. Any over-all usefulness will depend on the actual, not mythical, value of its function to each person.

The American nation has been described by sociologists as the only instance in which large masses of civilized mankind have enjoyed a regime of unqualified individualism. Modern mass production and mass distribution, city congestion and social structures of increasing complexity have restricted some of the industrial individualism that was America. The individualism of personality must be protected. Psychology of the future must apply itself to the study of values of human life and a proper regard for the need of aims, opportunities for individual interests and progress. Even a consideration of the role of esthetics in human contentment has been named as an important study. Apparently, sufficient social thought has not been directed to these fields.

THE NATIONAL HEALTH PROGRAM

The American Medical Association has long been a close observer of the government-controlled plans of foreign countries designed mainly for peasants and workers with low incomes and with a high percentage of indigency and little medical care. But the situation in America is different and American medicine is planning for a people who already have the highest quality of medical care in the world.

The National Health Program of the American Medical Association is a much broader program than any promoted by advocates of government compulsory plans. The program provides for the interweaving of all the agencies of community life to attain the maximum of results of health and happiness by voluntary effort and individual freedom, government aids to be utilized only in those areas in which the individual and the community require that assistance.

The American Medical Association program indicates the need for standards of nutrition, housing, clothing and recreation. It emphasizes the important of preventive medicine and public health service. Prenatal care, childbirth, infant welfare and child care are recognized as specialized services in which community effort is helpful. Hospitals and health centers are encouraged to meet the need of the communities they serve, and voluntary prepayment plans for hospital and medical care are promoted to finance adequate service. Veterans' care of good standard supplied to those with service-connected disabilities or in need are an obligation of good government. Medical research is fundamental to progress. The voluntary health agencies have developed uniquely in the United States. Health education and fulness of wholesome living round out our health program.

Let social groups now advocating foreign plans turn instead to the American Medical Association in the fulness of an American health program. Present unprecedented health standards are the accomplishment of American medicine in plans and effects, and they will continue to progress. Medicine must and will provide leadership in health.

THE WORLD MEDICAL ASSOCIATION

But medicine must be at the same time local, national and worldwide. Wherever man lives, health is important. The American Medical Association participated in the organization of The World Medical Association in Paris, France, on Sept. 18, 1947. Forty-seven nations were represented in this organization meeting. A meeting of the association will be held in Geneva, Switzerland, in September of this year.

Among the objectives of the World Medical Association are: (1) to promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means possible; (2) to study and report on the professional problems which confront the medical profession; (3) to organize and exchange of information on matters of interest to the medical profession; (4) to establish relations with and to present the view of the medical profession to the World Health Organization, UNESCO and other appropriate bodies; (5) to assist all peoples of the world to attain the highest possible level of health, and (6) to promote world peace.

The great world interest in this new medium of world understanding seems to assure an effective future for this organization. Its cooperation is essential to maximum functioning of the World Health Organization.

Medicine is the oldest of the professions. Man owes more of his present advanced status to medicine than to any other field of learning. Without freedom from attenuating disease and without sufficient days of life, education, culture and progress would have been impossible.

The consideration of health needs common to all nations, a better understanding and assistance in the development of the best possible medical service to the whole world is a new thought and an opportunity of promise. If medicine, the oldest and most effective service to man, can assist the world to a greater measure of health, given a reasonable opportunity for happy living, more progress may be made toward a lasting peace than government has been able to accomplish throughout years of war.

CONCLUSION

American medicine has grown to its present high position in science and its unequalled service to the public by progress under the principles set forth by the founders of the nation: (1) the greatest freedom of the individual to control his own personal matters not subservient to the state; (2) the provision to the individual patient of the best possible medical service by his individual physician, not by the political employee of the state; (3) the opportunity of the individual physician to progress to greater scientific attainments and better medical service, free from the deteriorating influence of government political control.

This, in analysis, is the spirit of the progress of American medicine.

SYMPATHECTOMY FOR ESSENTIAL HYPERTENSION

ARTHUR M. FISHBERG, M.D.
New York

In the past fifteen years, sympathectomy has been carried out for essential hypertension in several thousand patients. Notwithstanding the analysis of much of this material, not even an approach to unanimity as to the value of the operation has been attained. Opinions vary from the belief[1] that sympathectomy is indicated in a high proportion of patients with essential hypertension to the view[2] that the operation is of little more value than symptomatic management.

Almost all the larger series[3] of sympathectomies have been reported by surgeons who performed the operation on patients referred by different physicians. This paper is based on patients selected for operation by a single internist and followed by him after operation. The report thus represents an evaluation of sympathectomy from the point of view of a physician who is at the same time treating other—many more—hypertensive patients without operation and has thus a control in his own experience for assessment of the symptomatic results. The observations seemed, further, to throw light on the mechanism of symptomatic relief by sympathectomy, as well as on the pathogenesis of the cerebral and retinal manifestations of hypertension.

MATERIAL

The 119 patients had essential hypertension, so far as could be determined by means short of renal biopsy. When there seemed to be doubt whether the hypertension was essential or due to glomerulonephritis or pyelonephritis, operation was not performed. Two of the patients had Adson's[4] infradiaphragmatic sympathectomy, 8 Peet's[1] supradiaphragmatic operation and 109 Smithwick's[5] thoracolumbar sympathectomy.

SELECTION OF PATIENTS

Sympathectomy was advised or rejected on the basis of the following indications and contraindications:

Indications for Sympathectomy.—The clinical manifestations which mainly motivated the decision to operate were one or more of the following:

Headache was experienced by 83 patients. It was severe and not satisfactorily relieved by "medical treat-

ment." Most often the headache was so severe that the sufferer was willing to undergo operation merely for the relief of this one symptom, whether or not the hypertension was significantly reduced. Twenty-three patients had retinal lesions. Of these, 17 had papilledema, almost always with hemorrhages and exudates; 6 had hemorrhages and/or exudates; and 2 had thrombosis of a central vein. Congestive heart failure improved by preoperative treatment to a state of tolerable compensation with normal circulation time and venous pressure was present in 11 patients. Eight patients had cerebral hemorrhage; 8 patients restlessness and fatigability of incapacitating severity (never taken as the sole indication); 4 patients convulsions due to hypertensive encephalopathy; and 1 patient Raynaud-like symptoms. Nineteen patients were asymptomatic with high and rising diastolic pressure (over 130 mm. in a majority of repeated examinations).

Contraindications to Sympathectomy.—The patients operated on did not have any of the following contraindications: 1. Pronounced impairment of renal function. No patients were operated on in whom the nonprotein nitrogen of the blood exceeded 40 mg. per hundred cubic centimeters or who were unable to concentrate the urine to a specific gravity of 1.019 or more. 2. Congestive failure not relieved by treatment. However, several patients were operated on in whom gallop rhythm persisted. 3. Auricular fibrillation, flutter or heart block. After a patient with frequent ventricular extrasystoles not eliminated by quinidine died suddenly while being wheeled from the operating table, none with this arrhythmia were operated on. 4. Cardiac pain occurring paroxysmally, generally constricting in nature, relieved by glyceryl trinitrate and considered probably to indicate high grade coronary narrowing by arteriosclerosis with resultant coronary insufficiency. On the other hand, dull precordial ache often present for hours and unaffected by nitroglycerin was not taken as a contraindication. The reasons for the exclusion of patients with anginal pain soon after the beginning of the series were the sudden death of 1 such patient two days after operation from acute coronary insufficiency and the a priori probability that sudden fall in blood pressure may precipitate coronary insufficiency when the coronary arteries are much narrowed. 5. Evidence of widespread, high grade cerebral arteriosclerosis in the form of repeated cerebral vascular accidents, mental deterioration or depression. However, a single cerebral hemorrhage was not taken as a contraindication and sometimes was evaluated as favoring operation. 6. No patients were operated on in whom diastolic pressure did not exceed 110 mm. in a majority of repeated examinations. 7. Because of the probability of much arteriosclerosis, operation was not advised in patients over 55 years. In those between 50 and 55 years, operation was advised only with extreme circumspection and because of either insufferable headache or retinal lesions.

The effect of three hourly doses of 0.2 Gm. of "amytal sodium" on the blood pressure was observed preoperatively in most of the patients. The test did not prove of much help in selection of patients. There was some correlation between the fall in blood pressure resulting from the hypnotic and the outcome of the operation, but it was not close and there were many discrepancies. Moreover, pronounced fall in blood pressure repeatedly followed administration of "amytal sodium" in patients with nephritic hypertension or who were revealed by azotemia to be unsuitable for operation.

In deciding whether sympathectomy was called for, stress was laid on the analysis of the clinical picture into the part directly due to hypertension and that due to arteriosclerosis. Thus, hypertension and coronary arteriosclerosis are of varying relative importance in the pathogenesis of heart failure in different hypertensive patients. Likewise, hypertension and cerebral arteriosclerosis vary in their contribution to headache and other cerebral symptoms in persons with essential hypertension. Those symptoms which are due to arteriosclerosis will not be helped and may be aggravated by sympathectomy; e.g., coronary insufficiency following operation in persons with severe coronary arteriosclerosis and deep mental depression after sympathectomy in those with cerebral arteriosclerosis (both observed in this series). Smithwick's[6] observation that the results of sympathectomy are less satisfactory when the pulse pressure is high probably is explained by the high pulse pressure manifesting severe arteriosclerosis of the aorta and other large arteries.

BENEFITS OF SYMPATHECTOMY

Sympathectomy has both benefits and untoward effects; evaluation of the operation demands that advantages and disadvantages be counterbalanced. In these observations the benefits were as follows:

1. *Lowering of Blood Pressure.*—At the last measurement the diastolic pressure was 25 per cent or more below the preoperative level in 25 per cent of the patients and systolic pressure had fallen similarly in 32 per cent. In 18 per cent the last blood pressure reading was 150 mm. systolic and 100 mm. diastolic or less.

The most striking effect on the blood pressure was in the following case:

> A man of 36 years was known for three years to have essential hypertension. He had severe occipital headaches during this period. Preoperative blood pressure averaged 200 mm. systolic and 135 mm. diastolic; he had narrowed retinal arterioles with arteriovenous compression. He underwent thoracolumbar sympathectomy in December 1941. He has felt entirely well since recuperating from the operation and has worked hard. In October 1947, his blood pressure was 116 mm. systolic and 75 mm. diastolic.

From Table 1 it will be noted that in each age group the blood pressure averages lower than the preoperative level. The 119 patients had an average preoperative blood pressure of 218 mm. systolic and 135 mm. diastolic; at the last examination, which averaged thirty-two months after operation, the average blood pressure was 184 mm. systolic and 118 mm. diastolic. There was thus an average fall in systolic pressure of 16 per cent and in diastolic pressure of 13 per cent.

While the natural history of essential hypertension exhibits pronounced fluctuation in the blood pressure, the tension in untreated patients usually does not tend to fall over a protracted period. Inasmuch as almost all the patients in this series were given "medical treatment" for months or years before operation, it seems definite that the fall in pressure after the operation is the result of the sympathectomy.

In most patients the pressure falls close to normal for a postoperative period of weeks or a few months. This period is too brief to be of much significance, and is not included in the tables. Most often the pressure then gradually rises. However, in some the pressure has remained below 150 mm. systolic and 100 mm. diastolic for periods of observation up to almost six years (table 2). In interpreting the relatively high proportion of such satisfactory pressure levels in the group followed for between forty-nine and seventy-two months, it should be borne in mind that 20 patients—including those responding least well to sympathectomy—had succumbed at earlier periods. Moreover, 2 of these patients had had myocardial infarction long after the operation, which presumably participated in keeping the blood pressure down.

Systolic Blood Pressure Higher *	1	4	10	1	16
Diastolic Blood Pressure Higher *	1	8	11	1	21
Worth While Symptomatic Improvement *	4	23	29	3	59

* Findings at the last examination.

2. *Symptomatic Improvement.*—It is obviously difficult to assess symptomatic improvement. There is often great fluctuation in the symptoms of untreated patients; for no discernible reason, such symptoms as headache, *vertigo, restlessness and precordial pain may disappear* for months or years. However, once severe symptoms have set in, such spontaneous improvement for more than a few months is much the exception. Of the 119 patients, 100 had symptoms due to hypertension; of these 100, at the last examination there was symptomatic improvement which seemed "worth while" to me in 59. In others there was symptomatic relief for a shorter period, but symptoms of considerable severity had returned before the last examination; these results were not regarded as worth while in this evaluation.

TABLE 2.—*Results at Successive Periods After Sympathectomy*

Time After Operation (Months)	Patients	Blood Pressure Under 150/100 mm.	Diastolic Blood Pressure 25% Lower	Worth While Symptomatic Improvement	Deaths
13-24	40	10	13	22	10*
25-48	48	6	12	24	6
49-72	18	6	7	12	1
72 plus	3			1	1

*These 10 deaths occurred in the first twenty-four months (6 in the first year); they do not include 4 operative deaths.

The symptom most often relieved by the operation was headache. Of the 83 patients who suffered from headaches so severe that they were a factor in impelling operation, 64 had no or only slight headache up to the time of the last examination. Among those completely relieved were patients who had suffered from headache for five to fifteen years. Most often completely relieved was a type of headache especially apt to result from hypertension, namely, occipital headache frequently radiating down the back of the neck, present when the patient awakens, and often relieved after he gets up and about. Headache was repeatedly relieved in patients in whom there was little change in blood pressure.

Other cerebral symptoms of hypertension, notably restlessness, pounding in the head, inability to concentrate and vertigo, were also relieved in a high proportion of the sufferers. The convulsions of hypertensive encephalopathy did not recur in any of the 4 patients who had had them.

Impairment of vision due to retinopathy was several times improved.

These observations contain less data on the effect of sympathectomy on the cardiac symptoms of hypertension because patients with manifest heart failure or angina pectoris were excluded. However, in several instances gallop rhythm disappeared after operation, the inverted T waves indicative of left ventricular strain became upright, and the enlarged heart decreased in size. Dull precordial pain disappeared several times. In 1 patient not included in this series—a physician, who was operated on against my advice—high grade left ventricular failure, which had incapacitated the patient for months, cleared up so completely after operation that the patient has been able to practice actively for five years since.

No patients with significantly impaired renal function are included in this series. However, I have seen several persons with bad renal function who underwent sympathectomy on the advice of others; in none was the performance of the kidney improved. This is contrary to the findings of Peet and his associates,[1] who have observed improvement in renal function. The albuminuria of more than minimal degree present in 28 cases was not definitely affected.

3. *Clearing of Retinal Lesions.*—Few manifestations of hypertension imply a worse prognosis than neuroretinopathy. For this reason, the rapid improvement in the fundus that often follows sympathectomy is as significant as it is striking. Seventeen of the patients had papilledema, accompanied in 15 by hemorrhages and exudates. After operation, the papilledema, hemorrhages and exudates cleared (sometimes leaving residua) in 12 cases. In the 4 instances of longest duration of improvement, the disk and retina are still normal *seventy-one, sixty-nine, fifty-two and forty-five months* after sympathectomy. In 3 patients the retinal lesions recurred after complete clearing. Of the 17 patients with hypertensive neuroretinopathy, 10 are still alive. Of the 7 who died, 5 were patients in whom the fundus never cleared, while the remaining 2 succumbed to heart failure without recurrence of the retinal lesions.

4. *Economic Rehabilitation.*—Many of the patients who were unable to work for months prior to operation because of headache, restlessness, weakness or other symptoms were economically rehabilitated so that they returned to their occupation or household duties. Sometimes the rehabilitation was only transitory, but in others it has already lasted from two to six years. A dentist who was unable to practice for a year before operation put in a full day's work for four years after sympathectomy until he suffered a myocardial infarction; the headache and restlessness which had incapacitated him did not return.

5. *Prolongation of Life.*—The question whether sympathectomy prolongs life is difficult to answer because of inability to estimate even roughly what the duration of life would have been without surgical treatment It would seem that in those cases in which the blood pressure is strikingly and protractedly lowered with decrease in the size of the enlarged heart and disappearance of the electrocardiographic pattern of left ventricular strain, the operation should tend to prolong life. The best objective evidence that sympathectomy prolongs life in some patients is afforded, as pointed out by

Peet,[1] by patients with neuroretinopathy. For hypertensive neuroretinopathy (papilledema, usually with hemorrhages and exudates) to disappear completely in the natural course of the malignant phase of essential hypertension is so rare as to constitute a clinical curiosity, although it apparently occurs less rarely with rigid restriction of sodium chloride. Such clearing occurred in 12 of 17 cases. Moreover, of the 17 patients with hypertensive neuroretinopathy, 10 are still alive; 6 of these have survived over three years since operation. The 2 who have survived longest feel well and are without retinal lesions seventy-one and sixty-nine months after sympathectomy. Inasmuch as about 90 per cent of patients with papilledema due to essential hypertension succumb within two years, there would seem to be little doubt that sympathectomy has prolonged life, and usefully so, in some of these patients.

UNTOWARD EFFECTS OF SYMPATHECTOMY

Unfortunately, in addition to these benefits, sympathectomy also has its disadvantages:

1. The operative mortality in this series was 3.5 per cent. This mortality occurred notwithstanding that only patients were operated on who seemed to be as good surgical risks as can be expected in persons with severe hypertension. However, 1 patient who died early in the series had angina pectoris and would not now be operated on. But even the most painstaking selection cannot entirely eliminate the operative risk; another operative death occurred in an asymptomatic man of 40 years who was operated on only because his blood pressure had risen rather rapidly to 230 mm. systolic and 140 mm. diastolic.

2. Extensive thoracolumbar sympathectomy in two stages usually entails much postoperative discomfort or even suffering. In our cases the period of hospitalization averaged well over one month. Entry into the pleura, infection and other complications often aggravate the patient's ordeal.

3. Following operation there is often a period of many months or even a year or more in which orthostatic hypotension causes discomfort, although this can be mitigated by elastic bandages and lower abdominal compression. Neuritic pains in the back or of girdle-like distribution are sometimes severe for many months. Cold hands may be annoying.

4. The economic burden is often great. It is unusual for the patient to be able to return to his occupation in less than three months and often it is longer.

5. Resection of lumbar ganglions often results in absence of ejaculation with resultant sterility.

6. Sympathectomy is at best a palliative and not a curative procedure. Despite the frequently pronounced and protracted lowering of blood pressure and symptomatic improvement, not 1 patient in this series is regarded as "cured." In every instance, the last examination revealed evidence of hypertensive disease. In the large majority of instances the blood pressure was still definitely above normal. But even when frequent readings below 150 mm. systolic and 100 mm. diastolic were obtained, occasional rises above this level revealed the persistence of the underlying hypertensive disease. Further evidence of abnormal vasoconstriction in the areas not affected by the sympathectomy was narrowing of the retinal arterioles even in patients with lowered blood pressure.

7. Arteriosclerotic symptoms may be aggravated. A large proportion of patients with essential hypertension have advanced sclerosis of large arteries in various parts of the body. With the fall in blood pressure produced by sympathectomy, manifestations of inadequate blood flow through these narrowed arteries may first appear or increase. Two of the patients first experienced intermittent claudication of the lower extremities when arising after operation. In several instances angina pectoris first appeared within two years after operation, which produced much lower blood pressure, in patients without previous cardiac symptoms; there were 7 deaths from myocardial infarction. Several patients whose blood pressure had been lowered experienced severe depression after operation; 1 committed suicide. In these patients, who had not been depressed before operation, inadequate cerebral blood flow seemed the most likely explanation. When the arteriosclerotic symptoms first appeared soon after the operation, fall in blood pressure probably reduced the blood flow; in those in whom coronary insufficiency or other arteriosclerotic manifestations developed months or years after operation, progression of the arteriosclerosis was presumably the important factor. After the first year, deaths are most often due to arteriosclerotic complications in the heart or brain.

MECHANISM OF RELIEF OF HEADACHE AND RETINOPATHY

From table 1 it can be seen that at the last examination the blood pressure was below 150 mm. systolic and 100 mm. diastolic in 22 of the 119 patients. The diastolic pressure was 25 per cent or more below the preoperative level in 30 of the 119 patients (including all those with pressure below 150 mm. systolic and 100 mm. diastolic) or 25 per cent. On the other hand, worth while symptomatic improvement occurred in 59 patients. Since 19 of the 119 patients were asymptomatic before operation, worth while symptomatic improvement was obtained in 59 per cent of those with symptoms.[7]

Worth while symptomatic improvement thus occurred more than twice as often as did a fall in diastolic pressure of 25 per cent or more. Moreover, there were several patients with striking and protracted symptomatic improvement despite no fall in blood pressure or in whom the systolic and diastolic pressures were higher than preoperatively.

In the large majority of the cases, most of what is here termed "worth while symptomatic improvement" applies to headache and, less often, retinopathy. In most of the patients, headache, severe and frequent before operation, disappeared. One had almost continuous headaches for four months before operation and another frequent headaches for fifteen years; neither has had any headache in the more than two years since operation. In several cases headache, severe before sympathectomy, never returned despite the fact that the pressure remained high and the patient succumbed to cardiac or renal failure. Likewise, clearing of retinopathy was observed without fall in pressure.

The remarkable frequency with which headache and retinopathy are eliminated by sympathectomy has been noted since the first operations, but the mechanism of relief has not been entirely elucidated. Reduction in blood pressure and decrease in pressor response to emotional and other stimuli doubtless are primary factors in relief of headache and retinopathy ("albuminuric retinitis" never develops except in the wake of diastolic hypertension). But these mechanisms do not operate in the numerous cases in which headache and retinopathy vanish after operation despite little change in blood pressure

---

progressed.

or even a rise. Observations made in the course of this study indicate that the mechanism by which sympathectomy may relieve headache and retinopathy even when the blood pressure is unaltered is a redistribution of blood so that a smaller fraction of the cardiac output is distributed to the cephalic portions of the body with resultant decrease in blood flow to the head. The phenomena which bespeak such a redistribution of blood are:

1. After sympathectomy, the narrowing of the retinal arterioles present in severe hypertension persists. This is the observation which originally suggested that the often remarkable relief of the cephalic symptoms of hypertension by sympathectomy may be due to redistribution of blood with diminished cranial blood flow. It has been stated that the constriction of the retinal arterioles may be relaxed after operation. Despite careful comparative observations before and after sympathectomy for several years, I have not been able to detect such relaxation. The caliber of the arterioles has not been augmented by the operation, the narrowing present before sympathectomy persisting. This has been the case whether or not the blood pressure has been lowered and whether or not retinal lesions cleared up.

The persistence of the narrowing of the arterioles of the retina is really what one would anticipate, for this vascular territory is not denervated.

2. In at least the first months after operation the hands of the patient on whom sympathectomy has been done are generally cooler than before operation. Contrariwise, the feet are warmer. Normally, the hands are warmer than the feet, but this is reversed after adequate sympathectomy (table 3). The cold hands and warm feet indicate the redistribution of blood flow toward the caudal parts of the body.

TABLE 3.—*Skin Temperature Before and One Month After Thoracolumbar Sympathectomy*

	Preoperative	Postoperative

Ankle	85	93
Dorsum of foot	85	95
Toe	73	95
Sole	76	94
Heel	75	93

3. *Orthostatic hypotension may occur.* For months after operation fall in blood pressure in the erect posture with resultant giddiness and even blackouts may be an annoying feature. The denervation of the vessels in the caudal parts of the body prevents the reflex vasoconstriction which participates importantly in the maintenance of arterial pressure in the erect posture. The consequence is that assumption of the erect posture is accompanied by fall in arterial pressure, pooling of blood in the caudal parts of the body and decrease in cerebral blood flow.

The redistribution of the blood is a manifestation of the very nature of the operation. A primary function of the sympathetic innervation of the vessels is the regulation of the distribution of the cardiac output. Thus during exercise vasoconstrictor impulses over the splanchnic nerves divert blood to the extremities, while during digestion stimuli over the vasoconstrictor nerves of the peripheral vessels shift blood to the splanchnic area. Thoracolumbar sympathectomy denervates the vessels of the caudal but not of the cephalic parts of the body. The result is a change in the pattern of the peripheral resistance to blood flow which consists in diminution in resistance in the caudal regions of the body with no change (if not an increase) in the cephalic parts. The consequence can only be an increase in the fraction of the total cardiac output (known to be unchanged) which flows to the caudal parts of the body and a corresponding decrease in the volume of blood flow to the cephalic regions.

There are several clinical circumstances in which diminution in blood flow to the head seems to be associated with relief from hypertensive headache. Few hypertensive patients with pronounced heart failure complain seriously of headache. The development of heart failure in hypertensive patients with headache is accompanied by disappearance of the headache even though the diastolic pressure remains high. Phlebotomy has long been used to treat intractable hypertensive headache. Perhaps the most characteristic form of headache due to hypertension is one which awakens the patient in the morning after long hours of recumbency; such headache is frequently alleviated when the patient gets up and about, and Allen[8] pointed out that the headache can sometimes be averted by having the patient sleep with the head of the bed elevated.

The identity of the pain-sensitive structures responsible for hypertensive headache is not known. The fact that sympathectomy may relieve the headache without change in blood pressure points to the possibility that the headache is due to distention of and rise in pressure in the postarteriolar vessels (capillaries and veins). There is evidence (Cobb[9]) that the cerebral arterioles constrict as a result of nervous stimulation much less forcefully than the extracranial arterioles. In hypertension there may be, as a result of the less forceful constriction of the cerebral arterioles, a rise in cerebral capillary pressure, which decrease in blood flow to the head following sympathectomy tends to counteract.

Retinopathy.—The remarkable frequency with which sympathectomy is followed by disappearance of papilledema, exudates and hemorrhages has been observed before and was striking in these observations. Clearing of the retinopathy was observed not only in patients in whom the blood pressure was reduced, but also when the pressure did not fall or even rose. Thus, in a man of 53 years operated on too recently for inclusion in this series, headache present almost daily for five months before operation and retinopathy (papilledema, hemorrhages, exudates) have disappeared in the face of rise in blood pressure from a preoperative level of about 200 mm. systolic and 130 mm. diastolic to 230 mm. systolic and 140 mm. diastolic with peaks as high as 270 mm. systolic and 160 mm. diastolic.

Ophthalmoscopic observations before and after operation showed no increase in the caliber of the attenuated retinal arterioles in the patients in whom the retinal lesions disappeared. This observation does not agree with Volhard's[10] widely accepted theory that "albuminuric retinitis" is due to angiospastic ischemia of the retina. Since the constricted retinal arterioles do not relax after operation, it is hard to see how fall in blood pres-

sure would favor the clearing of retinal lesions of ischemic pathogenesis. These observations would seem, rather, to indicate that the retinal lesions are due to propagation of high arterial pressure to the retinal capillaries with resultant transudation and hemorrhage. They also suggest that the same mechanisms of fall in blood pressure and redistribution of blood flow away from the cephalic parts of the body which alleviate headache also lower the pressure in the retinal capillaries and venules with consequent regression of the papilledema, exudates and hemorrhages.

EVALUATION OF SYMPATHECTOMY

None of the patients here reported on was cured. From these observations, sympathectomy is a palliative and not a curative measure.

Although sympathectomy is only a palliative measure, many patients derived sufficient benefit from the operation to make it worth while. In deciding whether sympathectomy is advisable, the possible advantages and disadvantages should be counterbalanced for the individual patient. On the basis of the benefits and untoward effects observed in this series, the present status of sympathectomy appears to be as follows:

1. Sympathectomy should rarely be advised unless the patient has first failed to respond to rigid restriction of sodium chloride and to rest.

2. Sympathectomy is indicated in patients in whom a relatively rapid downhill course seems likely because of: (a) rise in diastolic pressure from a previously lower level to 130 mm. or more in several separate examinations; (b) papilledema, retinal hemorrhages or retinal exudates; (c) intractable headache; (d) cerebral hemorrhage or hypertensive encephalopathy; (e) heart failure overcome by treatment.

3. Sympathectomy is contraindicated in patients with impairment of renal function severe enough to be documented by azotemia or pronounced diminution in concentrating ability. Sympathectomy is generally inadvisable in patients with congestive heart failure not overcome by treatment, although 1 patient with severe pulmonary engorgement due to left ventricular failure has had remarkable improvement with economic rehabilitation for the first five years since operation.

4. Sympathectomy is contraindicated in patients whose symptoms are due to arteriosclerosis of the heart, brain or extremities; aggravation of these symptoms may result from abrupt fall in blood pressure. Because of the great frequency with which the complaints of hypertensive patients past 50 years are due to associated arteriosclerosis, sympathectomy is rarely indicated at this age. None of our patients was 55 years or more.

5. Sympathectomy is not indicated in asymptomatic patients in whom the diastolic pressure is consistently below 130 mm. In such cases the chances of useful and comfortable life for five, ten and not rarely more years seem to me more than to counterbalance the risks and untoward effects of the operation. Moreover, in these observations there has been little correlation between the duration of the hypertension and the success of the operation. Asymptomatic patients can be placed on suitable restrictions and watched, and sympathectomy can be advised if the pressure rises or severe headache or retinal lesions appear.

Discovery of essential hypertension in a youthful subject is not per se an indication for operation. Most patients in whom hypertension is discovered in their teens or early twenties have more than a decade, most often probably two or more decades, of well-being before them. Moreover, there is no certainty that sympathectomy will be successful in youthful subjects. The operation was performed on an asymptomatic youth aged 17 whose hypertension was of two years' duration; the blood pressure of 175 mm. systolic and 120 mm. diastolic has changed little in the five years since.

Using these criteria, the writer recommended sympathectomy in about 4 per cent of the patients with essential hypertension seen in the past year. In view of the fact that some were referred because operation was under consideration, in general practice the proportion would probably be smaller. Helpful and even life saving though sympathectomy is to some patients, at present it fills only a small gap in the great therapeutic problem of essential hypertension.

SUMMARY

One hundred and nineteen patients with severe essential hypertension were selected for sympathectomy and followed by the same observer for an average of thirty-two months. There were 4 operative and 18 subsequent deaths. The diastolic pressure was reduced 25 per cent or more in 30 patients. Worth while symptomatic improvement occurred in 59 per cent. Headache was the symptom most often relieved. Retinopathy cleared in 12 of 17 patients. Headache and retinopathy may disappear after operation without fall in blood pressure. It is suggested that the reason why cephalic manifestations (headache, retinopathy) of hypertension are the most favorably affected is that sympathectomy results in a redistribution of the cardiac output with a smaller fraction going to the cephalic portions of the body. The results of sympathectomy offer evidence that rise in pressure in the minute vessels of the brain and retina is of great importance in the pathogenesis of hypertensive headache and retinopathy. Sympathectomy is a palliative and not a curative procedure. After a weighing of the favorable and untoward effects, it is concluded that sympathectomy is indicated in less than 4 per cent of patients with essential hypertension.

RHEUMATIC FEVER IN CHILDHOOD

William Weston Jr., M.D.
Columbia, S. C.

The voluminous literature that has appeared in the last few years confirms the observation made by Sir Thomas Watson in 1843 that rheumatic fever is a disease of childhood. It also suggests that the many reported cases of heart disease appearing at different periods of life have their origin in rheumatic fever of childhood—thus a pediatric problem.

Rheumatic fever is an acute or chronic systemic disease probably of infectious origin characterized by fever, joint, muscular, skin and nervous manifestations which frequently involves the heart and has a tendency to recur.

HISTORY[1]

Hippocrates was credited by Chomel with describing acute arthritis. The term rheumatism was first used by Ballonius (Baillou) (1535-1616), but his work appeared in 1642 posthumously. Sydenham gave the first satisfactory clinical description of the differential diagnosis between acute rheumatism and gout in 1676. What is known as Sydenham's chorea was described by him a few years later. Independently and about the same time, in 1789 Jenner and Pitcairn gave lectures in which

Read before the Section of Pediatrics at the Ninety-sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

[1] Wilson, M. G.: Rheumatic Fever, New York, The Commonwealth Fund, 1940.

they demonstrated the association of rheumatism with heart disease. In 1833 Bouillaud emphasized the constant association of rheumatism and heart disease, stressing the frequent occurrence with rheumatism of both endocarditis and pericarditis. Wells first described subcutaneous nodules in 1810. Bright in 1831 recorded erythematous rashes in association with chorea and its close "affections of the pericardium." Sir Thomas Watson in 1843 "recognized rheumatic fever as essentially a disease of childhood." Cheadle, Sturges, Barlow, Lees, Garrod, Poynton, Payne, Coombs and Mantle are the names associated with this disease in the latter part of the last century and the first part of this century. MacLagan first emphasized the salicylic drug as of benefit in rheumatic fever in 1876. In 1904 Aschoff described the specific interstitial myocardial lesions usually called "Aschoff bodies."

ETIOLOGIC FACTORS

The etiology of this disease has not been determined. It is truly a research problem which a number of investigators have undertaken, but indisputable confirmatory evidence. has not been presented. Jones[2] and other authors have pointed out in connection with rheumatic fever that the original focus of onset depends on the implantation of the hemolytic streptococcus A group, usually in the upper respiratory tract. There is almost conclusive evidence that the hemolytic streptococcus is a causative agent, but the mechanism remains obscure. Lichtwitz[3] expressed the opinion that rheumatic fever is a noninfectious disease and is not caused by specific micro-organisms which may be pathogenic or nonpathogenic. He directed attention to the similarity between serum sickness and a certain type of rheumatic disease which might indicate that the sensitizing antigens may also arise in response to foreign proteins that are not of microbic origin. The subject of sensitizing is brought out clearly by Coburn,[4] who stated the belief that there is an abnormal response to the hemolytic streptococcus in the rheumatic subject, implying both the genetic and the conditioning factor, and he outlined the response to the attack. Three soluble antigenic principles are produced in vitro; namely, erythrogenic toxin, fibrinolysin and streptolysin.

A virus organism as the cause of this disease is doubtful; it now appears that the weight of evidence and most authorities believe hemolytic streptococcus group A which produces an antigen that acts in a sensitizing manner is the chief cause of this disease.

CONTRIBUTORY CAUSES

Heredity.—Heredity is an important factor. Approximately 5 per cent of all children fall into the genetically susceptible group. The gene follows the mendelian recessives, which is clearly demonstrated by Wilson's[5] diagram, used by her permission and that of the publishers.

Nutrition.—An analytic study of the diet of our patients reveals that the carbohydrates are high and the proteins low. It has been demonstrated that when patients with rheumatic fever are given a nutritious diet it tends to prevent recurrences[6] The foods suggested were eggs (particularly yolks), meat, milk and calcium:

Economic and Environmental Factors.—The majority of these cases are found in the poorer class. In all classes faulty diets may be discovered. Poor housing, improper clothing and unhygienic surroundings are important contributory factors. Exposure to sudden changes in temperature with dampness increases susceptibility to respiratory and other infections. Coburn[4] called attention to the fact that the mortality from rheumatic fever is much higher in England than in the Netherlands. He expressed the opinion that it is not the environment or the climate but dietary deficiencies which are responsible.

TABLE 1.—*Prediction Chart for Childhood Rheumatism**

Mating	Expected No. Rheumatic Children Before Ocurrence of Rheumatic Child	Expected No. Rheumatic Children After Occurrence of Rheumatic Child
Both parents positive	All (nearly)	All
One parent positive, the other parent's relatives as follows:		
One parent or many siblings positive	One half	One half
One sibling or many aunts and uncles positive	One third	
One aunt or uncle positive	One sixth	
Both parents negative but one grandparent of each line positive	One quarter	One quarter
Both parents negative and rheumatic fever remote or absent in relatives	Unlikely	

*Based on the interpretation of a single recessive gene.

INCIDENCE

Rheumatic fever has the highest mortality among the diseases of children. Its distribution is universal, but it is more prevalent in cold damp climates than in those that are warm and dry. This observation may be illustrated as far as the United States is concerned by a graphic chart, "Studies in Rheumatic Fever," by The Metropolitan Life Insurance Company,[7] which shows a high incidence of rheumatic fever in the New England states and certain of the Rocky Mountain states and a low incidence in the Midwestern and Southern states (fig. 1).

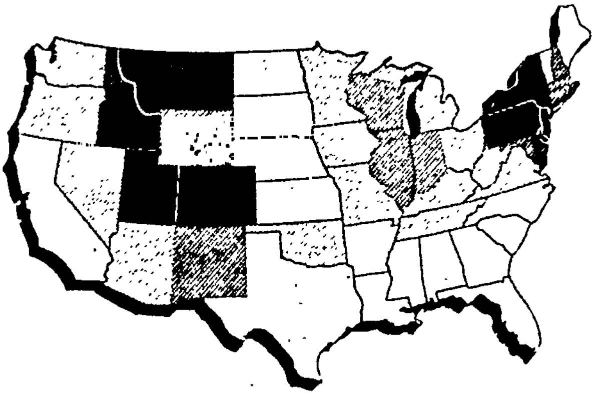

Fig. 1.—Map showing death rates from rheumatic fever for the years 1939 to 1941 among white persons aged 5 to 24 years. Solid black, very high rate (9 or more per hundred thousand); heavy diagonal bars, high (7 to 8.9 per hundred thousand); light diagonal bars, medium (5 to 6.9 per hundred thousand); white, low (under 5 per hundred thousand). A relative concentration of rheumatic fever in certain areas is evident. Rates of sickness from the disease in army camps show a less definite pattern but are generally highest in the Rocky Mountain area. (Chronic rheumatic heart disease is included.)

The work which the American Council on Rheumatic Fever of the American Heart Association, Inc., is doing deserves commendation; the results of the investigation of these organizations has stimulated physicians to greater study and more careful investigation by emphasizing the prevalence and seriousness of rheumatic fever. Consequently many unsuspected cases are being discovered. Some aspects of the disease are well known and clear but others are puzzling, so that it deserves careful study in the hope of finding out more about the disease. Added interest is being shown in rheumatic fever because the experience in the recent war revealed a great many cases. "Preliminary study shows the rejection rate for rheumatic fever, including history of rheumatic fever, was approximately 3 per 10,000."[8] "Also preliminary data, pending final analysis of medical records, shows that there were approximately 17,900 cases of rheumatic fever reported in the Army during the period 1942-1945 inclusive."

[7] Studies in Rheumatic Fever, New York, Metropolitan Life Insurance Company, November 1944, p. 12, chart 9, no. 1.

There are probably more than 1,000,000 cases of rheumatic fever in the United States, with at least one half of the total, or 500,000 cases, among children.[9] "In Boston and New York, about one half the cases with rheumatic heart disease who were subjected to special review had a history of rheumatic fever or chorea in childhood."[10]

A survey of school children in Dublin, Ga., revealed organic heart disease in 1.5 per cent. Rheumatic heart disease was found in 1 per cent of all school children examined, 1.26 per cent of the white children and 0.60 per cent of the Negro children. The incidence of rheumatic fever was 2 per cent, 2.10 per cent among white children and 0.60 per cent among Negro children.[11] This again shows that white children are more susceptible than Negro children.

Yueda,[12] in a ten year review of autopsies at the Charity Hospital in New Orleans, Jan. 1, 1935, to Jan. 1, 1945, discovered 167 cases of rheumatic fever, which is 1.35 per cent. These figures are practically the same as those for Northern cities. He concluded that Negroes are not more susceptible but the disease is more severe, particularly among the Negro females. In 39, or 24 per cent of these cases, the findings were incidental and there was no clinical evidence or diagnosis of rheumatic fever.

SYMPTOMS AND SIGNS

When a child presents itself with obvious cardiac or choreic manifestations the diagnosis may be considered established. It is the borderline cases which one must carefully investigate. A history of present or past manifestations and laboratory findings is essential in order to arrive at a correct diagnosis, because there is no single positive test on which one can determine a diagnosis. The recording of easy fatigue, insomnia, restlessness, anorexia, failure to gain, emotionalism, anemia and repeated epistaxis with low grade fever suggests a chronic disease, and rheumatic fever should be considered. Jones[13] in his classifications of rheumatic fever listed various manifestations which he divided into two groups:

A. Major manifestations:
    1. Carditis
    2. Arthralgia, migrating joint arthritis
    3 Chorea
    4. Subcutaneous nodules
    5. Recurrence of rheumatic fever
B. Minor manifestations:
    1. Fever,
    2. Abdominal pains
    3. Precordial pains
    4. Rashes
    5. Epistaxsis
    6. Pulmonary findings
    7. Laboratory findings

Morgan[14] described a prerheumatic stage in children presenting these symptoms: tendency to become easily fatigued, bouts of unexplained fever, listlessness, restlessness, particularly in sleep and failure to gain weight. These signs are more apt to occur during the spring and in damp weather.

Coburn[4] describes three definite phases in rheumatic fever in which he named the manifestations and the duration of each; these are: (1) invasion or onset; (2) quiescence, and (3) active rheumatic fever.

Rheumatic fever may be monocyclic, polycyclic or continuous; Griffith[15] described four clinical types of rheumatic fever: (1) acute fulminating type; (2) subacute polycyclic type; (3) subacute monocyclic type, and (4) subclinical type.

Growing pains have been considered of too little significance. Kohn and Lingg[16] in following cases in which growing and articular pains were manifested found that one third showed definite evidence of rheumatic fever within a year and that within three years 50 per cent showed other manifestations of rheumatic fever. Abdominal pain is a common symptom, also muscular pains in the arms and more frequently the legs. Repeated stumbling when running followed by pain in the legs is significant. Apfel[17] stressed abdominal and muscular pains, particularly in the hamstring, calves and shoulder group.

In an examination of 3,129 cases[16] of rheumatic fever as to the type of onset, polyarthritis was found in 1,262 or 40.3 per cent. Gibson[18] stated that in 60 to 70 per cent of patients showing polyarthritis rheumatic carditis developed. Chorea as a manifestation of rheumatic fever has been shown clearly by Jones and Bland[19] and many others.

Examination and reexamination of the heart are important, while the interpretation of the signs and sounds heard are of equal significance. The child should be stripped to the waist so that the cardiac area may be well investigated. Palpation for thrills and a maximum impulse should be made, and percussion for the size of the heart. Intrinsic and functional murmurs which are unrelated to true cardiac disease are rather common in children. Auscultation should begin at the base in order that the sounds may be timed properly. In the beginning of the disease the soft systolic murmur is heard best over the apex; it is usually transmitted to the axilla. As the disease progresses the middiastolic murmur is heard. This means the involvement of the mitral valve. As the disease progresses one must be mindful of a pericardial involvement. The child should be examined in recumbent, upright and lateral positions and in different phases of respiration, particularly on deep inspiration, in order to rule out cardiorespiratory murmurs or functional murmurs which are not of any significance. When a persistent diastolic murmur is heard regardless of the position or the stage of respiration it invariably means valvular involvement which may be congenital acquired or both.

Gibson[20] emphasized the importance of the presystolic murmur heard over the apex in rheumatic heart disease. The systolic and diastolic murmurs may disappear while this third murmur persists.

It is sometimes necessary to have a stethogram[21] made in order to have the correct interpretation of the murmurs heard.

DIFFERENTIAL DIAGNOSIS IN RHEUMATIC FEVER

There are several diseases which may be confused with this disease; 1. In rheumatoid arthritis, the enlarged spleen and the failure to respond to salicylates are two differentiating features. 2. Septic arthritis is differentiated by aspiration of purulent fluid from the involved joint. 3. In syphilitic hydrarthrosis the involvement of the joint persists and the Wassermann reaction is positive. 4. In sickle cell anemia, the joints fail to respond to salicylates and there is sickling of the red blood cells. 5. In poliomyelitis there is a generalized anesthesia in the beginning, stiffness in the neck and some changes in the spinal fluids. 6. In lupus erythematosus exposed areas are involved, particularly the bridge of the nose; there are leukopenia, microscopic hematuria and shallow ulcers on the buccal mucous membrane. 7. In undulant fever there is specific agglutination or a positive reaction to a cutaneous test, and usually a low sedimentation rate. 8. Ova of parasites are found in stools. 9. In dengue fever, the joints do not swell and there is a poor response to salicylates.

PATHOLOGIC CHANGES

The characteristic Aschoff bodies are usually not seen after the first attack of rheumatic fever, but the mesenchymal tissue is involved. There is an increase of vascular permeability with an involvement of the connective tissue spaces in the myocardiam, with also a change in the connective tissue of the endocardiam and under the serous layers[22]. Necrosis soon follows which is a fibrinoid degeneration of the collagen fibrils; this is followed by a characteristic cellular response. The fibroblastic proliferation is apt to continue and in turn is followed by the appearance of multinucleated cells, so-called Aschoff cells. New fibrous tissue is produced and the valves are likely to be involved. Experimentally[23] bodies simulating Aschoff bodies have been produced by intravenous injection of heterologous serum proteins.

The pathologic changes[24] resolves themselves into chronic inflammatory lesions of the collagen connective tissues involving most often the heart and also the joints, subcutaneous tissues, brain and other organs.

PROGNOSIS

The prognosis will depend on ability to have provided suitable environmental surroundings, a proper diet and probably a change of climate. The early medication by large doses of salicylates and rest in bed. The outlook even under the most favorable circumstances depends on the seriousness of the attack with particular reference to cardiac damage, the grade of chorea and the number of reinfections. May G. Wilson[1] in her review of 673 children with rheumatic fever found that the average duration of life after cardiac decompensation was only 2.8 years, and that after a congestive heart failure chances of surviving beyond the second decade are less than 1 in 3.

TREATMENT

Prompt recognition and early treatment are of the greatest value. There should be careful history taking, culturing of inflamed throats, observation for manifestations of chorea and appropriate treatment in the incipience of the attack. It is probable that a possible disabling illness could be prevented.

Patients with active disease must be given complete bed rest until all signs of decompensation have cleared.

TABLE 2.—*Summary of Management of Patient with Rheumatic Fever*

Examination	Laboratory examinations
History	R.B.C. and W.B.C. differential hgb.
Temperature, pulse and respiration	Sedimentation rates
Weight	Urinalysis; exam. of stool
General appearance and general physical exam.	Search for sickle cells in all Negro patients
Examination of heart with patient in recumbent and sitting positions	Electrocardiogram
	Roentgenogram in A. P., lateral and right oblique
	Vaginal smear
	Agglutination series
	Swab (probably should have routine throat cultures)
Diagnosis	
Recommendations: hospitalization; foster homes; convalescent homes, or to be sent home	
Treatment: rest; exercise; salicylates; sulfadiazine; vitamins and diet	
Date of return visit	

The temperature should have remained normal for sufficient periods and other symptoms abated before exercise is allowed, and the sedimentation rate should be within normal limits. Perhaps the sedimentation rate is the best indicator now available for determining retardation or activity of the disease. Convalescent serums are of doubtful value. Repeated small transfusions have proved useful. Suitable environment which permits ample sunshine is essential.

Diet has not been sufficiently emphasized, as most patients show deficiencies in essential elements; even total calories are often insufficient. Foods procured from natural sources having vitamins, proteins and mineral elements in such proportions as to meet the requirements of nutrition should be given. The element calcium, which is deemed of great importance, should be derived from milk and the green leafy vegetables, and in order that the proteins contain essential amino acids that are not synthesized in the body the source should be meats, whole grain cereals and milk. Vitamin C is necessary to normal nutrition and is best obtained from citrus fruits. If an idiosyncrasy exists to one or more citrus fruits I suggest ascorbic acid.

The climatic change is of questionable value unless the patient is going to remain in the climate that has proved of benefit, because return to a colder climate may lead to recurrence. If the patient is to be returned to a different climate, preventive therapy should be instituted, provided the patient does not become drug (sulfonamide) sensitive.

24. Robinson, J. J., and Currens, J. H.: Preliminary Observations on Some Children with Rheumatic Heart Disease Transported to a Subtropical Climate, J. Pediat. 28:426 (April) 1946

The exercise of rheumatic patients must be limited and should be under competent medical supervision. At any signs of an interruption in convalescence such as dyspnea, fever or rapid pulse, activity must be stopped and a functional test applied.

Chemotherapy.—Salicylates in large doses are indicated[25] Taran[26] has shown that excellent results are obtained with the drug by mouth; he expressed the belief that the intravenous route is hazardous in children. The blood level should be 35 mg. per cubic centimeter, which can be derived by use of 1½ grains (0.1 Gm.) per pound (0.5 Kg.) of body weight. The benefit of sodium bicarbonate with the salicylates is debatable, and I think that aluminum hydroxide might be substituted for the sodium bicarbonate. Recently it has been suggested that the enteric salicylates produce a toxic effect, but I have not had this experience.

Penicillin has not given good results. Streptomycin has not been used in cases of rheumatic fever so far as I am aware. The sulfonamide drugs are contraindicated in the cases of active disease. Specific therapy such as the application of heat locally is good, but the use of artificial heat in the electric cabinet is of doubtful value.

Digitalis often saves a life in cases of decompensation. When it is used a sufficient amount should be given to digitalize the heart promptly. Sedation in the form of barbiturates or codein is often necessary. Oxygen will frequently tide the patient over from an extreme condition to a less severe one until the heart can pump sufficient oxygen to ventilate the system.

Paracentesis in pericardial effusions may be necessary to relieve cardiac embarrassment. Diuretics are not often employed but when indicated may be helpful.

Gratifying results in reducing the number of recurrent attacks by the use of sulfonamide drugs have been reported.[27] In the administration of the sulfonamide drugs toxic effects such as leukopenia, rashes, nausea and vomiting, icterus and agranulocytosis must be watched for.

INACTIVE RHEUMATIC FEVER

The preventive feature is an essential. This can be largely augmented by three methods: 1. Sulfonamide drugs should be administered in sufficient doses to prevent recurrent infections of the upper respiratory tract of the hemolytic streptococcus A group. Frequently daily doses of 0.5 to 1 Gm. will suffice. Blood sulfonamide levels around 1.0 to 3 mg. per cubic centimeter will often be enough, but this may vary with the individual patient. It is best to continue administration of sulfonamide drugs throughout the year, as exacerbations may occur in the summer, as was shown by Wolf, Rauh and Lyon.[28] The toxic effects have almost been nil, but a patient receiving this drug should have white blood cell counts and determinations of hemoglobin and of sulfonamide levels in the blood every two to four weeks. Urinalysis should be done at frequent intervals. Periodic administration of the drug may cause patients to become sensitive. 2. A suitable diet should be instituted as previously recommended, with sunshine and environmental improvement. 3. The psychosomatic condition must be cared for, as depressions in these children occasionally develop and deter their progress considerably.

Fig. 2.—Organization plan for a rheumatic fever program.

Studies[1] made of the relation of tonsillectomy to rheumatic fever convince me that the removal of tonsils gives little assurance of preventing either an initial attack or recurrence. When the operation is considered repeated throat cultures should be made, a urinalysis made and a satisfactory nutritional state established. The operation should not be performed when the disease is active. Should the precautionary measures not be observed operation may result in serious harm.

If the tonsils are diseased and apparently harbor the focus of infection they may be removed at an appropriate time. Small quantities of sulfonamide drug should be given. Kaiser[29] reported that the tonsils act as a storehouse for vitamin C, and they function as a filtering plant in preventing systemic infections.

The use of specific hemolytic streptococcus, mixed or typhoid vaccines has not produced encouraging results, nor have serums or blood from persons who have recovered from rheumatism prevented recurrence.

DETECTION OF CASES

Rheumatic fever should be a reportable disease; until such time it is going to be difficult to distinguish the doubtful from the actual cases of rheumatism.

When there is a confirmed diagnosis of rheumatic fever made in a child it is time to investigate the parents and other siblings. This method of examining the whole family is usually called screening, a difficult task. It means careful medical insight and requires much time and tact. Physicians must profit by the setup of the antituberculosis organizations, as they are known to have accomplished great good. Their results have shown a general decline in mortality since the first world war.

Examination of all school children should be compulsory. The voluntary examination of children by Jackson[30] and his group in Iowa disclosed several cases which otherwise might have escaped notice until it was too late to give the child much relief.

The problem of controlling rheumatic fever is one that belongs to the entire community (fig. 2). It is a collective and cooperative one. Armstrong and Wheatley[31] have offered excellent suggestions and plans for the approach with a concrete example as to the management of such a scheme or outline. It is a local community affair which should be popularized under well trained professional leadership. It is the cooperation of numerous persons and organizations, acting through an executive committee, from which satisfactory results will be obtained.

Fig. 3.—Organization of the rheumatic fever program in South Carolina, May 1947.

NOTES ON CASES

In a series of 50 patients, of whom 32, or 64 per cent, were white and 18, or 36 per cent, were Negro, the severe cardiac damage was 30 per cent more common among the Negro patients and the decompensation was twice as great.

My associates and I now have under observation 4 patients with active chorea, 3 white girls aged 4 to 12 years and 1 Negro girl aged 10 years. Two of the white girls and the Negro girl are having their second attack. No cardiac or valvular disease has been observed in the white girls, while the Negro girl shows definite disease of the mitral valves.

The results of the cardiograms have not been entirely satisfactory, as there have been only 4 patients among the 15 who have had definite rheumatic carditis who show prolonged intervals and irregularities. Our cardiologist examines each patient and thinks that we should use three chest leads instead of one to get a true picture; however, it demonstrates to me that though there is valvular involvement the myocardium and conductive mechanism have not been affected; that signifies that attacks in this climate are less severe.

The organization of our rheumatic fever clinic has been too recent to give any statistics, but it is manifest that cases of rheumatic fever exist in South Carolina, which was demonstrated by Beach and Ravenel[32] in 1944. I reported 30 cases in the same year.[33]

SUMMARY

As a result of improved diagnostic information and widespread interest rheumatic fever has been found to be more prevalent than formerly suspected. It has been shown that heredity is an important factor. Great emphasis is placed on nutrition. In no other disease is the satisfaction of normal nutritional requirements more essential as a means of restoring health. Environmental and hygienic surroundings occupy an important position in the restoration of health.

The salicylates should be administered within the limits of tolerance in the cases of active rheumatism. The measures suggested for disabling manifestations are of primary importance. It is suggested that the administration of sodium bicarbonate with the salicylates be abandoned and that aluminum hydroxide be substituted. The sulfonamide compounds have a definite field of usefulness in the prevention of recurrent rheumatic fever.

My observation is that rheumatic fever is not so common among Negroes as among whites but more severe.

ABSTRACT OF DISCUSSION

Dr. Ira Gore, Washington, D. C.: My experience has been limited to work in the etiology and pathology of this condition with respect to which Swift's views, regarding the importance of streptococcic infections and hypersensitivity to them, have been widely accepted. Recent bacteriologic work, though, has shown that steptococci are not a homogeneous species. There are eleven groups, of which group A is the one of etiologic significance. Within group A there are forty subtypes, much as there are subtypes among pneumococci. During the recent war, a commission studying hemolytic streptococcus diseases reaffirmed the relation of group A streptococci to the causation of rheumatic fever. They indicated that the disease never occurred in the absence of a previous infection by this organism. Several types were found capable of producing the rheumatic fever state with no one type predominating. The importance of reinfection by other types of group A organisms was stressed. Moreover, such a reinfection, provable by laboratory means, could be rather insidious, without clinical manifestations. In a significant number of their cases, abnormal electrocardiograms and elevated sedimentation rates were found during the interval preceding the onset of rheumatic fever; there was no true latent period. In another group of 185 carefully studied cases of streptococcus A infections of the respiratory tract, 2 exhibited similar abnormalities of the electrocardiogram, and sedimentation rate, but these manifestations were not accompanied by arthritis. The commission argued the essential identity of the two groups, the one group with arthritis and the other group without arthritis. But here caution and further investigation are indicated. Distinct anatomic differences are present between the cardiac changes which are frequent in scarlet fever and those found in rheumatic fever, and yet these cases of streptococcus A infection, too, are associated with abnormalities in the electrocardiogram and in the sedimentation rate. Whether they provide the anatomic background on which rheumatic fever develops, one cannot say, but certainly such changes are much more frequent than rheumatic fever following scarlet fever. Furthermore, the anatomic changes in 35 fatal cases of myocarditis following acute tonsillitis and nasopharyngitis are quite at variance with those of rheumatic fever. Though these cases lack the careful bacteriologic studies which would identify them unequivocably with those studied by the streptococcus commission, on a frequency basis alone there can be little doubt that many of them should be included.

[33] Weston, W., Jr.: Rheumatic Fever, South. M. J. 38:189 (March) 1945.

Dr. Stanley Gibson, Chicago: Dr. Weston called attention to the major and minor phenomena of rheumatic fever as outlined by Dr. Duckett-Jones, and I am sure we all agree with him. However, it is not always easy to be sure whether we have even one of those major phenomena. Take, first of all, polyarthritis In the typical case of rheumatic polyarthritis, in which several joints are involved, with redness and tenderness of the joints, fever and a prompt response to salicylates, one has little doubt of the diagnosis of rheumatic polyarthritis, and I think the diagnosis can be made on that one manifestation alone However, there are many cases that are less clear; for example, the child who has some nondescript pains, the mother being not quite sure whether they are in the joints or in the muscles, oftentimes only in the legs rather than in the arms and the legs. Those cases require careful study, and one should be careful about making a diagnosis of rheumatic polyarthritis on such a basis. In proportion as the pains are in the muscles rather than the joints, and when they involve only the legs rather than the arms and legs, I think one should be still more suspicious of a diagnosis of rheumatic fever. Ordinarily, there is little doubt about the diagnosis of chorea, though one sees many jittery children that are suspected of having chorea and sometimes are given this diagnosis on insufficient grounds. I like to think of Sydenham's chorea as disease which has a definite beginning, a continuance of weeks or months and a definite ending, so that at the end of the time the child is again well so far as the nervous system is concerned. I would also like to know that along with the incoordination of movement the child also has an emotional instability which is an integral part of chorea. Rheumatic nodules, another major manifestation of rheumatic fever, seldom help diagnosis, because the child who has nodules has a chronic and usually severe rheumatic infection, and the diagnosis does not depend ordinarily on the finding of a rheumatic nodule. They are of prognostic rather than of diagnostic importance. In regard to the heart, disease in which is the fourth major manifestation of rheumatic fever, I think again there are pitfalls. Too often, rheumatic heart disease is diagnosed on the presence of a murmur. If one keeps in mind the pathologic changes, it is only certain sorts of murmurs that are indicative of rheumatic heart disease. The two valves most severely and commonly involved are the mitral valve and the aortic valve. The mitral valve gives the systolic apex in the beginning; later a middiastolic and perhaps later a presystolic murmur. Those murmurs are at the apex, and that should be emphasized. As regards involvement of the aortic valve, the diastolic murmur of aortic insufficiency is distinctive once it is well heard, and unless one can hear these typical murmurs, I do not believe one should diagnose rheumatic heart disease, at least on the basis of auscultation.

Dr. Rachel Ash, Philadelphia: Dr. Weston emphasized the seriousness of rheumatic infection in childhood. I should like to illustrate this point by showing what happened to a group of 536 rheumatic children in Philadelphia. Ten years after onset of the disease, 25 per cent have already died of rheumatic infection. Moreover, the majority of persons presenting no functional incapacity are those who showed no clinical evidence of heart disease at the time of the initial attack. However, the incidence of carditis and of deaths was greater among those children taken ill during the period 1922 to 1926 than during the period 1927 to 1931, and least of all among those taken ill between 1932 and 1936. The decrease in carditis has not been due to any variation in the method of using salicylates. Throughout this period, it has been the custom of my associates and me to administer large doses of salicylates at the beginning of the disease, but not to continue their use in the absence of fever or articular pains. About ten years ago, we did try long-continued use of salicylates in about 10 children on our convalescent ward, and in that group, as in repeated isolated instances throughout the years, we have witnessed the development of carditis and of recurrences while large doses of salicylates were being administered. Whereas in the early part of this period, the majority of the children were returned home shortly after the disappearance of acute symptoms, these children are now kept in the hospital for an average period of three months or longer. Whether the lessening of severity of disease during this period is partly due to the favorable influence of prolonged bed rest at the onset of the infection or is entirely due to a spontaneous change in the character of the disease can be subject to speculation only, but I think that one should give prolonged bed rest the benefit of the doubt and not be tempted to try the recently instituted army treatment of early ambulation. The problem of controlling rheumatic fever is definitely one that belongs to the entire community. In establishing a community program, however, the education of the physician and the establishment of provisions for the care of the rheumatic child should precede publicity campaigns directed to the lay public. Such publicity campaigns do harm when they present a description of symptoms, often minor and not specifically rheumatic, which arouse neurotic fears. Because of publicity campaigns which have emphasized the most serious aspects of rheumatic infection, the diagnosis of this disease carries an emotional connotation which produces a state of panic in the minds of parents. It should not be made lightly on the basis of inadequate evidence.

Dr. Mark P. Schultz, Bethesda, Md.: Insufficient attention is, perhaps, directed to the importance of growing pains. The differentiation of pains, growing pains, as they are called, into rheumatic and nonrheumatic varieties seems most important, and it seems to me that there are some criteria which may be of help; namely, the increased severity of such pains when they are of nonrheumatic origin. It has often been observed that pains in the extremities which have later proved not to be rheumatic are severe enough to cause children to cry, whereas actual pain of such severity on a rheumatic basis is rare. Also, the rheumatic pains are more apt to occur during the day or during periods of physical activity, whereas most of those of nonrheumatic origin are more in evidence when the patient is at rest. The rheumatic pains are also more apt to be articular or juxta-articular rather than involving muscular structures. Another point might be mentioned. We physicians take an extremely optimistic view of the possibility that the agents which we use in rheumatic fever are actually curative. This should particularly be borne in mind with respect to the salicylates. When the antipyretics were introduced, we were most optimistic about their possible curative effects in rheumatic infection, but during the years, however, despite the use of antipyretics, including sodium salicylate in heroic doses, the conclusion was rather universally accepted that such drugs were purely symptomatic in their effect in rheumatic fever. The introduction, about 1935, of the administration of salicylates by the intravenous route has raised this question again. I feel, on the basis of my own observations, that there is no reason to alter the conclusion reached years ago, that their effect is essentially that of affording relief of symptoms. The data which have been cited as indicating a contrary conclusion were in large part collected from military personnel of an age not particularly susceptible to the progress of cardiac lesions. Dr. Ash mentioned the contribution of Drs. Robertson and Schmidt, who tried the experiment of not restricting physical activity in rheumatic patients. They found that patients admitted with rheumatic fever, when permitted complete physical activity at their own volition from the time of their admission until their discharge except during the periods of cardiac decompensation, recovered more promptly on the whole than those whose activities were curtailed. They pointed out that strict avoidance of restriction of activity eliminates the establishment of cardiac neuroses which are not to be eliminated in children when so much attention is paid to restriction of their activities. I think this raises a serious question, whether in the past we have been too extreme in the restriction of activity of rheumatic children.

Dr. William Weston Jr., Columbia, S. C.: I tried to get some data from reports in the occupied territories, and Dr. Paul White, who is permanent head of investigation in Czechoslovakia, wrote me a letter that he did not think that the incidence of rheumatic fever or carditis had changed much, but there were a great many cases in camps. The psychiatric condition which develops, which Dr. Schultz has just mentioned, is important, and when there is any doubt in the diagnosis of rheumatic fever, it behooves pediatricians to call an internist who is trained in cardiology to substantiate it. I did not mention the treatment in regard to penicillin but I noticed a good many—Dr. Keefer men-a cast and the use of crutches was begun. The use of cast and crutches was continued for one year. This patient also had 6 Gm. daily of "promizole" (4,2′-diaminophenyl-5′-thiazolylsulfone) for the first eight months of this year. No benefit was detectable when she was reexamined. The sedimentation rate, which had been 30 mm. per hour (Westergren method) at the time of biopsy, was 45 mm. per hour one year later. At this time streptomycin treatment was begun. The patient received 0.5 to 1 Gm. a day by intramuscular injection in divided doses every four hours. This dosage was continued for eighty-four days until a total dose of 58 Gm. of streptomycin had been given (fig. 1*a*). Within two and a half months the sedimentation rate dropped to 7 mm. per hour. When the patient was last examined, eighteen months after streptomycin therapy had been stopped, the sedimentation rate was 4 mm. per hour. Six months after administration of streptomycin had been begun (fig. 1*b*), swelling and soreness had completely subsided and full motion of the knee had returned. Six months after streptomycin therapy had been stopped, the patient was taken off crutches and allowed full use of the knee (fig. 1*c*). She has been jumping, running and playing without restraint for one year (eighteen months since streptomycin therapy was stopped), with full use of her left knee and no recurrence of pain, swelling or other symptoms. Our impression is that this was a favorable response to streptomycin.

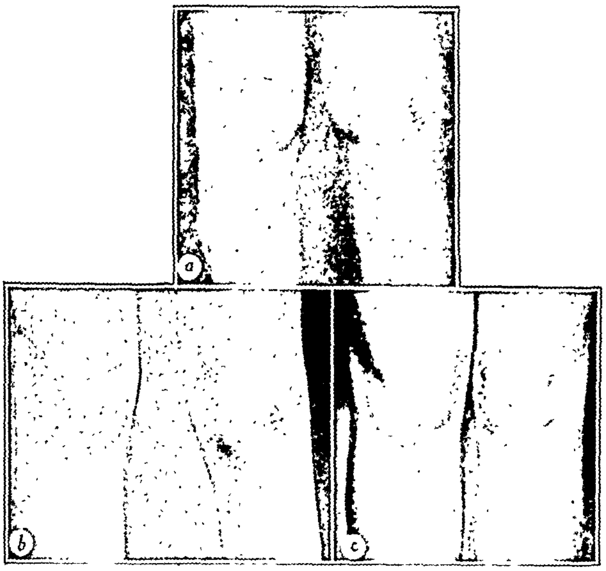

Fig. 1.—(*a*) Swollen, boggy-appearing left knee one year after biopsy and after one year in a cast without weight bearing. (*b*) Three months after cessation of streptomycin therapy. Complete subsidence of soreness and swelling and a return of a full range of motion. (*c*) Six months after cessation of streptomycin therapy. Continued normal appearance and function of left knee. (Reproduced from motion picture film.)

Case 2.—A white man aged 24 years had synovial tuberculosis of the right knee, demonstrated by histologic examination of the tissue from the knee on Dec. 14, 1946. There was no roentgenologic evidence of involvement of bone. A roentgenogram of the thorax revealed minimal active tuberculosis of both apexes. Specimens of sputum were positive for acid-fast bacilli before streptomycin was given, and became consistently negative within a few weeks after the start of therapy. The right knee had been swollen and painful for one year and the motion was limited between 90 degrees and 165 degress (fig. 2*a*). Administration of streptomycin (2 Gm. intramuscularly daily in divided doses every four hours) was started on Dec. 25, 1946, and was continued for ninety-one days for a total of 182 Gm. of streptomycin. In addition, once weekly for thirteen weeks 0.3 Gm. of streptomycin in 6 cc. of isotonic solution of sodium chloride was injected into the joint. This invariably provoked some local soreness, swelling and increased heat, which gradually subsided in two to three days. Strict rest in bed was carried out for three months, although the patient was allowed to move the knee about freely. Within one month of the start of streptomycin therapy (fig. 2*b*) the swelling and pain had almost completely subsided and there was nearly a complete range of motion. Three months from the start of streptomycin therapy, a full range of motion had returned. The patient has been using the knee for six months since streptomycin therapy was stopped with no return of swelling, pain or limited motion. The pulmonary lesion is stabilized. Our conclusion is that this was a favorable response to streptomycin.

Case 3.—A Negro aged 22 years had advanced destructive changes of all bony surfaces of the right knee, as revealed by roentgenographic examination. The knee was swollen, tender, with considerable increase in temperature and painful on the slightest movement. A roentgenogram of the thorax revealed bilateral far advanced tuberculosis, largely of the exudative type with positive sputum. Because of the extreme destruction of the knee, streptomycin therapy was started in preparation for arthrodesis. Histologic examination of the tissue, culture and guinea pigs inoculated with material from the knee were all indicative of tuberculosis. Administration of streptomycin (2 Gm. intramuscularly daily in divided doses every four hours) was started and continued for one hundred and twenty-two days for a total of 244 Gm. of streptomycin. In addition, 0.4 Gm. of streptomycin was instilled into the joint at weekly intervals for fifteen weeks. At the end of this time, the knee was definitely improved. Swelling had subsided considerably. There was no pain with motion, and the patient walked without complaint. Arthrodesis was still advised because of the pronounced destruction of the joint, the economic background of the patient and the distinctly improved but still active bilateral pulmonary disease. Cultures on three occasions and five pairs of guinea pigs inoculated at approximately weekly intervals with the material from the knee were positive for tuberculosis for the first seventy-seven days of streptomycin therapy. After this, two cultures and six guinea pigs inoculated with the material from the knee two months apart were negative for tuberculosis.

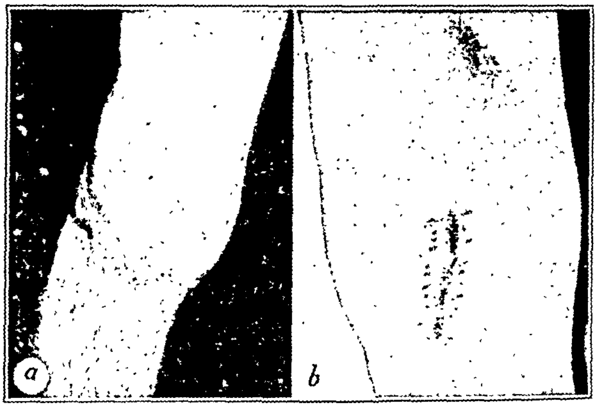

Fig. 2.—(*a*) Swollen, boggy, painful knee for past year. (*b*) One month after biopsy and start of administration of streptomycin. Pronounced reduction in swelling and pain and increase in range of motion.

The patient went home for one month and then returned for arthrodesis of the knee on May 24, 1947, and for a second course of streptomycin (0.5 Gm. intramuscularly every twelve hours for sixty-eight days). The incision healed by primary intention and ankylosis seemed solid within four months. The patient was fitted with a stiff leg brace, which he now wears. Remarkable clearing of the roentgenogram of the thorax occurred under streptomycin therapy and sputum became negative for acid-fast bacilli. Our conclusion is that this was a favorable response to streptomycin in that the thoracic lesions cleared considerably and streptomycin proved a valuable aid to operation on the knee.

Case 4.—A Negro woman aged 33 years has destructive tuberculosis of the right knee, which was demonstrated by histologic examination of tissue taken for biopsy at the time of arthrodesis on Jan. 21, 1947. She had two courses of streptomycin therapy, each of three weeks' duration. The first course of streptomycin (1.5 Gm. intramuscularly daily in divided doses every four hours) was begun at the time of arthrodesis. Sinuses developed after arthrodesis and have continued to drain to the time of writing. The second three week course of streptomycin

(1 Gm. intramuscularly every twelve hours) was given two months after the first at the time of the change of the cast. Our impression is that the patient derived no benefit. Treatment in this case was prophylactic.

CASE 5.—A white woman aged 21 years had progressive tuberculosis of the spinal column with a paravertebral abscess. A smear of the sinus of the back was positive for acid-fast bacilli in 1944. A roentgenogram of the thorax revealed a Ghon complex on the left side. In 1934 spinal fusion had been done for destructive arthritis of the bodies of the first to the fourth lumbar vertebrae. In 1945 a second spinal fusion was done for progressive involvement of the bodies of the eighth to the eleventh thoracic vertebrae with a paravertebral abscess The patient continued to have thoracic spinal pain. One year after the second spinal fusion the patient received streptomycin for seventy-seven days (1.6 Gm. intramuscularly daily in divided doses every twelve hours) for a total of 123 Gm The patient has continued to have thoracic spinal pain Our impression was that streptomycin had not produced benefit in a late and extensive lesion.

CASE 6.—A white girl aged 17 years had progressive destructive arthritis of the bodies of the ninth, tenth and eleventh thoracic vertebrae. A smear from the sinus of the back was positive for acid-fast bacilli. The patient had three spinal fusions—in 1940, in 1943 and April 5, 1947. Streptomycin (1 to 2 Gm. intramuscularly daily in divided doses every four hours) was given for one hundred and sixty-two days beginning one month before the last spinal fusion for a total of 211 Gm. A draining sinus at the operative site has persisted to date. Our impression was that streptomycin did not produce benefit in this case.

CASE 7.—A white man aged 59 years had tuberculosis of the bodies of the tenth, eleventh and twelfth thoracic vertebrae. Roentgenograms of the thorax were negative for tuberculosis. Cultures of postoperative sinuses were positive for tubercle bacilli. In 1936 the patient underwent thoracotomy for what was believed to be an empyema of the left side of the thorax. This turned out to be a paravertebral abscess from tuberculosis of the bodies of the tenth, eleventh and twelfth thoracic vertebrae. Multiple sinuses formed postoperatively and drained for eleven years. The patient was totally disabled. Administration of streptomycin (0.25 Gm. intramuscularly every six hours) was started on March 28, 1947, and was continued for ninety-seven days and a total of 97 Gm. of streptomycin. Within seventeen days all sinuses healed; they have remained healed for six months. Spinal fusion was done on July 17. Healing of the incision was normal, and convalescence to the time of writing has been uneventful. Our impression is that this was a favorable response to streptomycin.

CASE 8.—A white woman aged 45 years had tuberculosis of the bodies of the ninth and tenth thoracic vertebrae. Roentgenograms of the thorax were negative for tuberculosis. Culture of draining sinuses of the right femoral region of three and a half years' duration was positive for tubercle bacilli. Sinuses developed after aspiration of a psoas abscess pointing in the femoral triangle. A spinal fusion on Jan. 30, 1946, had been unsuccessful, as the grafts absorbed, the sinuses continued to drain and the destructive process in the vertebral bodies progressed. Administration of streptomycin (0.5 Gm. intramuscularly every six hours) was started on Sept. 12, 1946, and continued for one hundred and sixty-six days. Treatment was stopped for two months after one week of administration of streptomycin because of a rash on the legs and arms, chills, fever, nausea and vomiting. Desensitization doses of streptomycin were restarted after one week until 2 Gm. daily was being given. This was continued until completion of the treatment at the end of one hundred and sixty-six days without event. Three months after the start of the streptomycin therapy the sinuses healed; they have remained healed for five months. On April 10, 1947, a second spinal fusion was done. Postoperative convalescence has been uneventful to date. Our impression is that this was a favorable response to streptomycin.

CASE 9.—A white girl aged 13 years had tuberculosis of the right ankle involving the subastragalar joint, later involving the tibioastragalar joint, and tuberculosis of the left elbow. A roentgenogram of the thorax revealed calcified hilar nodes and a calcified lesion in the upper lobe of the left lung. The patient was first seen at the clinic in 1944 because of cervical adenitis present since 1939 and an axillary adenopathy present since 1941, along with intermittent swelling and soreness of the right ankle and the left elbow. She was seen again July 14, 1945, at which time triple arthrodesis was done on the right ankle for destructive arthritis. Tissue removed at examination was positive by histologic examination and culture for tuberculosis. Healing of the incision and ankylosis of the region of triple arthrodesis were uneventful. On May 2, 1946, arthrodesis of the left elbow was done for progressive destructive arthritis. Healing and postoperative course were uneventful. On Aug. 7, 1946, roentgenographic examination revealed a spread of the tuberculous process into the tibioastragalar joint with pain and swelling, for which arthrodesis of this joint was done. One week prior to this, administration of streptomycin (1.2 Gm. intramuscularly daily in divided doses every four hours) had been started. This was continued for one hundred and three days for a total of 124 Gm. Convalescence was uneventful. Examination March 10, 1947, revealed a solid fusion of the ankle joint on which arthrodesis had been done. Eight months after administration of streptomycin was stopped the patient is clinically and roentgenographically cured. She has no pain or other symptom from the ankle or elbow. Our impression is that this was prophylactic treatment. No conclusions can be drawn as to benefit of streptomycin, as two previous arthrodeses healed uneventfully without benefit of streptomycin; however, clinically the patient gained weight and appears much improved.

CASE 10.—A white woman aged 28 years had tuberculous tenosynovitis of the right ankle, tuberculosis of the right sternoclavicular joint with a draining sinus and pulmonary tuberculosis with tuberculous empyema, a bronchopleurocutaneous fistula and multiple draining sinuses of the thorax. Tuberculosis was proved in 1942 by histologic examination of tissue from the thorax and cultures from the sinuses. The diagnosis of tuberculous tenosynovitis must be considered presumptive, as no biopsy, culture or studies on guinea pigs were carried out on the swollen soft tissues about the ankle. Roentgenograms of the ankle were negative for osseous changes, Thoracoplasty and an unroofing operation were done in 1942 to obliterate and unroof the empyema cavity and to stop the draining sinuses. The sinuses continued to drain. The patient received "promizole" orally (6 to 10 Gm. daily) and "promizole" jelly locally from November 1943, through March 1944, without benefit. A cold abscess developed under the right breast during this period of treatment. Swelling over the lateral aspect of the right ankle, pain and limited motion continued. This patient had two courses of treatment with streptomycin. The first was begun Dec. 29, 1944, and continued for twenty-one days, 1.2 Gm. being given intramuscularly daily in divided doses every four hours for a total of 25 Gm. of streptomycin. At this time no more streptomycin was available. Administration of penicillin (100,000 to 200,000 units intramuscularly daily in divided doses every three hours) was started and continued for twenty-seven days. By this time the sinuses were almost completely closed and the patient went home.

The patient returned for further treatment Feb. 8, 1946, at which time she was considerably improved—only a small amount of drainage from the thoracoplasty scar remained. The bronchopleurocutaneous fistula was still present. Her right ankle was asymptomatic although still slightly swollen. Administration of streptomycin (1.2 Gm. intramuscularly daily in divided doses every four hours) was started and continued for sixty-four days for a total of 77 Gm. Nebulization of streptomycin mixed with penicillin (0.5 Gm. of streptomycin and 200,000 units of penicillin in 30 cc. of sodium chloride solution daily) was also started at the same time. Nebulization was stopped after seven days because it produced paroxysms of coughing. At this time the patient was unable to blow air through the bronchopleurocutaneous fistula for the first time in four years! The empyematic space was almost entirely obliterated by the sixty-fourth day and the patient was dismissed. She returned six months later, at which time the empyematic space was entirely healed. She made no complaints about the ankle. One year since administration of streptomycin was stopped the patient's thorax remains entirely healed and the ankle appears normal. Our impression is that this was a favorable response to streptomycin.

Case 11.—A white man aged 68 years had synovial tuberculosis of the right ankle demonstrated histologically by biopsy of swollen tissue over the tip of the lateral malleolus. The ankle had been swollen and painful for six or seven months. A roentgenogram of the ankle revealed no changes of bone. A roentgenogram of the thorax showed no abnormality After biopsy, the ankle drained for four months. Streptomycin therapy (1 Gm. intramuscularly daily in divided doses every six hours) was started and continued for one hundred and five days and a total of 105 Gm. of streptomycin. Swelling and pain in the ankle diminished during streptomycin therapy. The patient is still under treatment. Our impression is that improvement of the patient under treatment is noted.

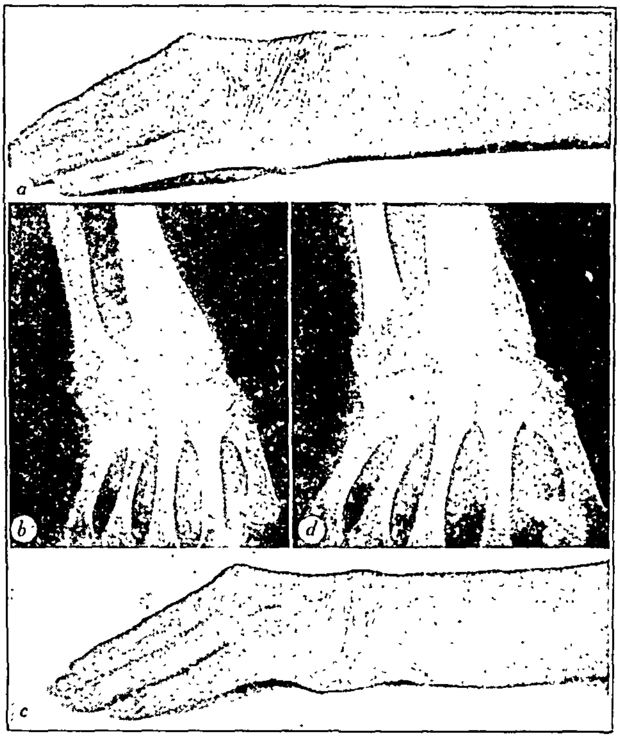

Fig. 3.—(*a*) Painful swelling of wrist of fourteen years' duration (*b*) Appearance before start of administration of streptomycin. Destruction of wrist joint, carpal bones and proximal ends of metacarpal bones. (*c*) Nine months after cessation of streptomycin therapy Swelling has subsided. (*d*) Appearance nine months after cessation of streptomycin therapy Recalcification evident

Case 12.—A white man aged 39 years had tuberculosis of the right wrist proved by histologic examination, culture and inoculation of guinea pigs. He had a swollen, painful wrist of sixteen years' duration Roentgenograms of the wrist revealed advanced destruction of all carpal bones and articular surfaces of the lower end of the ulna and the radius. A roentgenogram of the thorax revealed minimal inactive tuberculosis in the apex of the right lung. Streptomycin therapy (1 2 Gm. intramuscularly daily in divided doses every four hours) was started and continued for sixty-six days and a total of 72 Gm. A cast was applied to the wrist for four months. Two days after streptomycin therapy had been stopped, a sinus developed on the ulnar side of the wrist; this drained for several months. Swelling and pain subsided considerably during treatment. The roentgenogram revealed considerable recalcification of the involved bones of the wrist. Eighteen months after administration of streptomycin had been stopped the patient reported (by letter) that the wrist is "still swollen some" but not painful and there has been no drainage. Our impression is that this was a fair response to streptomycin.

Case 13.—A white woman aged 58 years had a painful swollen wrist of fourteen years' duration (fig. 3*a*). Tuberculosis was proved by inoculation into guinea pigs of material from the wrist. A roentgenogram of the wrist revealed pronounced destruction of the lower 1 inch (2.5 cm.) of the radius and the ulna, the carpal bones and the proximal ends of the metacarpal bones (fig. 3*b*). A draining sinus had been present for four months. A roentgenogram of the thorax revealed inactive fibrous and calcified tuberculosis of both apexes. Administration of streptomycin (1.2 Gm. daily intramuscularly in divided doses every four hours) was started Jan. 26, 1946, and continued for fifty-seven days and for a total of 61 Gm. A cast was applied for four months. The sinus continued to drain for six months after administration of streptomycin had been stopped. Nine months after cessation of streptomycin therapy the wrist was no longer swollen (fig. 3*c*) and roentgenograms revealed recalcification of the carpal bones (fig. 3*d*). Eighteen months after administration of streptomycin had been stopped the patient reported that there was a little swelling and pain at times. Our impression is that there was a favorable response to streptomycin despite the short duration of treatment.

Case 14.—A white girl aged 6 years had destructive arthritis of the carpal bones of the right wrist with swelling and pain of six months' duration. Histologic examination of tissue taken from the wrist for biopsy was positive for tuberculosis and a smear was positive for acid-fast bacilli. A sinus persisted for four months after biopsy. A roentgenogram of the thorax did not reveal tuberculosis. Administration of streptomycin (about 0.5 Gm. intramuscularly every twelve hours) was started Sept. 10, 1946, two weeks after biopsy, and was continued for eighty-five days and a total dose of 80 Gm. of streptomycin. A cast was applied to the forearm and hand and maintained until eight months after administration of streptomycin had been stopped. At this time the wrist was clinically healed with no redness or swelling. A roentgenogram revealed recalcification of the carpal bones. Our impression is that this was a favorable response to streptomycin.

Case 15.—A white man aged 58 years had draining sinuses of both shoulders of several years' duration. A roentgenogram of the thorax revealed far advanced bilateral pulmonary tuberculosis. Smears of sinus material and sputum were positive for acid-fast bacilli, and cultures of the sputum were positive for tuberculosis. Administration of streptomycin (0.25 Gm. intramuscularly every six hours) was started Nov. 2, 1946, and continued for one hundred and twenty days for a total of 120 Gm. Within one month of the start of administration of streptomycin, both sinuses of the shoulders closed; they have remained so five months after cessation of streptomycin therapy. Two months and four months after streptomycin therapy had been stopped, however, sternal and scapular abscesses developed, and drainage has persisted to the time of writing. Streptomycin therapy has not been resumed. The patient's pulmonary status is unchanged. Our impression is that this was a favorable response to streptomycin in the shoulders.

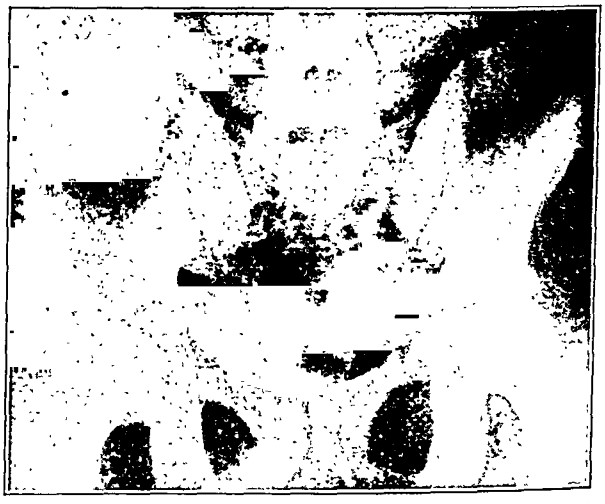

Fig. 4.—Appearance of tuberculous lesion of the body of fourth lumbar vertebra and iliac bone.

CASE 16.—A white man aged 25 years had tuberculosis of the fourth lumbar vertebra and the right ilium (fig. 4) proved by inoculations into guinea pigs of pus from a psoas abscess in the right femoral triangle. Roentgenograms of the thorax revealed no abnormality. The patient had complained of pain in the right iliac region for two years. Roentgenograms of the lumbar portion of the spinal column revealed questionable narrowing of the fourth lumbar interspace. Biopsy of the iliac lesion was advised and carried out. Considerable purulent material welled from the incision when the abdominal muscles were stripped from the medial side of the ilium in obtaining a specimen for this biopsy. Cultures and inoculations into guinea pigs of this material were positive for tuberculosis. Administration of streptomycin (0.5 Gm. intramuscularly every twelve hours) was started Aug. 14, 1947, and continued for one hundred and twenty days for a total of 120 Gm. of streptomycin. Drainage had diminished to a drop or two in a day after two months of streptomycin therapy. The patient was still under treatment at the time of writing and the drainage has remained the same. The lesion in the right ilium has remained unchanged in appearance by roentgenographic examination. There has been some progression of the disease in the fourth lumbar interspace with minimal destruction of the right side of the inferior portion of the body of the fourth lumbar vertebra. Our impression is that the patient improved under treatment.

SUMMARY

Sixteen patients with tuberculosis of bones and joints have been treated with streptomycin. Three patients had involvement of multiple joints. Nineteen ioints were involved. Sinuses were present in 4 cases before streptomycin therapy was begun. The average duration of treatment was one hundred and twelve days. The average total dose of streptomycin (0.75 to 2 Gm. daily) was 134 Gm. Mild to moderate toxic symptoms were found in 9 of 16 patients. In only 1 patient were symptoms severe enough to warrant discontinuing administration of the drug.

Response to streptomycin was considered favorable in 9 cases and fair in 1 case; there was no benefit in 4 cases, and the therapy was too recent to evaluate in 2 cases.

CONCLUSIONS

Considering the great difficulty which has been encountered in the treatment of similar conditions in the past, we are encouraged by this preliminary survey.

It is felt that 1 Gm. of streptomycin daily for ninety days is a satisfactory course of treatment in the light of present knowledge.

Radioactive Isotopes and the Microscope.--From the chain reacting piles of the Atomic Energy Commission have come radioactive isotopes which have been termed the most important tool for research in biology and medicine since the introduction of the microscope....However, it appears that in this field the most important contributions of radioactive isotopes will be in elucidating our understanding of the more fundamental mechanisms of diseases. At present there is no evidence that nuclear energy offers a cancer cure, and such predictions as have promised this are totally unrealistic and inaccurate. It appears that knowledge may be gained on the more fundamental mechanisms by which cancer develops, and such knowledge could lead to improved methods of cancer treatment. To explore further the role that nuclear energy may play in increasing our knowledge of cancer, the Atomic Energy Commission had launched a comprehensive program in this field.--Dr. John Z. Bowers, U.S. Atomic Energy Commission, From an address read before the National Convention of the Institute of Radio Engineers, New York, March 23, 1948.

CHOLANGIOGRAPHY IN STONE STRICTURE AND OPERATIVE INJURY OF BILIARY DUCTS

C. R. HUGHES, M.D., J. R. HANNAN, M.D., and
B. E. MULVEY, M.D.
Cleveland

A review of our experience with cholangiography in 90 consecutive patients who have had exploration of the common duct for stone, stricture or stenosis of the biliary tract emphasizes that: 1. Cholangiography is an accurate means of determining the presence or absence of disease in the biliary ducts. 2. Roentgen visualization of the biliary tree following the injection of an opaque medium is a simple diagnostic procedure. 3. More positive information can be obtained by cholangiography than by surgical exploration of the biliary ducts. 4. It is essential and advantageous to employ cholangiography at the time of operation. By this procedure lesions not evident to the surgeon may be demonstrated and reoperation avoided. 5. Postoperative cholangiograms are necessary to confirm the absence of disease in the duct system before the T tube is removed.

INDICATIONS FOR CHOLANGIOGRAPHY

The indications for cholangiography at the time of operation are essentially the same as those proposed by Lahey[1] and others for open exploration of the biliary tract. If any of the following conditions apply, it is believed that the ducts should be explored, and hence cholangiography is indicated: (1) if the patient is jaundiced at the time of operation or if there is a history of jaundice in the past; (2) if multiple small stones are found in the gallbladder at operation; (3) if the ducts are dilated or obviously diseased; (4) if a stone in the duct is suspected on palpation; (5) if a small fibrotic gallbladder is discovered; (6) if bile aspirated from the duct is muddy, or (7) if the liver is cirrhotic.

As Lahey[2] has indicated, a negative history of jaundice is not a trustworthy criterion for avoiding exploration of the common duct. There was no history of jaundice, and none was present at the time of operation in 39 per cent of a large series of his patients who later proved to have stones in the common or the hepatic duct.

In a minority of patients the indications for open exploration are not so clearcut, and the surgeon hesitates to subject his patient to the added risk of opening the duct system. That choledochostomy is not undertaken without added risk has been pointed out by Lahey (1932),[1] who estimated that the mortality in simple cholecystectomy was about 4 per cent, whereas the mortality jumped to 13 per cent if, in addition, the common duct was opened. Cole (1939)[3] using figures assembled from various sources, estimated that the over-all mortality in cholecystectomy was 6.5 per cent, but if choledochostomy was added the operative mortality rose to 10 per cent. Both of these estimates indi-

cate that unnecessary exploration of the bile ducts is to be avoided. In this borderline group of patients cholangiography at operation can be of great value. Through its use unnecessary exploration of the ducts can be avoided, or if pathologic changes are demonstrated by the cholangiogram, corrective surgical measures can be introduced immediately (fig. 1).

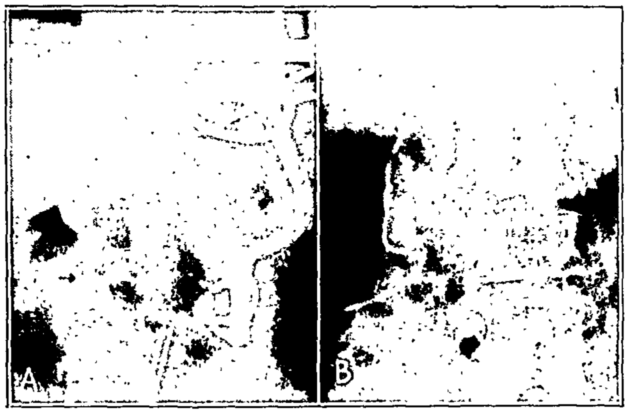

Fig. 1.—A—Cholangiogram made at time of operation. It shows obstructive dilatation of duct system with defect at distal end of common duct due to stone. B—Postoperative cholangiogram made two weeks after removal of stone. It demonstrates patency of common duct with residual slight dilatation of duct system.

We should like to add still another reason for the more frequent use of immediate cholangiography. If there is any reason to suspect injury to the bile ducts during operation, it is of fundamental importance to visualize the ducts before the abdomen is closed. Indeed it would seem logical to employ cholangiography even when the technical approach seems simple, as Gray[4] has suggested that the mobility of the ducts in uncomplicated cases increases the likelihood of their being pinched, kinked, ligated or transected during the isolation and ligation of the cystic duct and artery.

Since exploration of the common duct is practically always followed by T tube drainage of the duct, delayed cholangiography can, and should, be repeated at intervals after the operation until the bile ducts have returned to a normal or postoperative physiologic state. Rather frequently the common duct remains abnormally dilated for a considerable time after removal of obstructing duct calculi. In all of these cases postoperative cholangiography can demonstrate a return of the ducts to normal size and tone and will thereby furnish reliable information on which to base discontinuation of T tube drainage (fig. 2).

In most of our cases the T tube was left in the common duct one month; however, if the cholangiogram showed continued dilatation with delayed emptying of the common duct, the T tube was left in place for a second month or occasionally longer when indicated. We know of no instance in which the T tube has led to recurrence of stones or formation of stricture.

Stones not demonstrated at the time of the first operation can usually be detected by postoperative cholangiography. Likewise, changes occurring after operating—i.e., strictures, postoperative inflammatory narrowing of the ducts—can be visualized. Spasm of the sphincter of Oddi can usually be differentiated from organic obstruction by the relaxation of the spasm following the use of one of the nitrites.[5]

METHODS[6] EMPLOYED IN IMMEDIATE AND DELAYED CHOLANGIOGRAPHY

In our experience we have found that more can be gained by actual delineation of the hepatic ducts, and in many cases the radicles, by rapid injection into the T tube using a syringe. Over the years we have tried a variety of opaque mediums and at present are satisfied with 35 per cent iodopyracet solution. When the injection method is employed the dye enters the ducts so rapidly that the relatively small opening through the ampulla does not permit rapid transit into the duodenum. Intraductal pressure accordingly rises enough to allow complete filling of the hepatic ducts and radicles. We have had no serious ill effects from the utilization of this method in well over one hundred cholangiograms. Roentgenoscopic control is utilized in the delayed examination. In this manner overdistention of the ducts can be prevented. A spot roentgenogram is taken under fluoroscopic control during the injection of the first few cubic centimeters of dye. The injection is repeated as regular 10 by 12 inch (25.4 by 30. cm.) or 14 by 17 inch (35.6 by 43.2 cm.) films are exposed. Films are exposed fifteen minutes and thirty minutes after injection to determine the amount of dye remaining in the biliary tree. During this half hour the T tube is clamped.

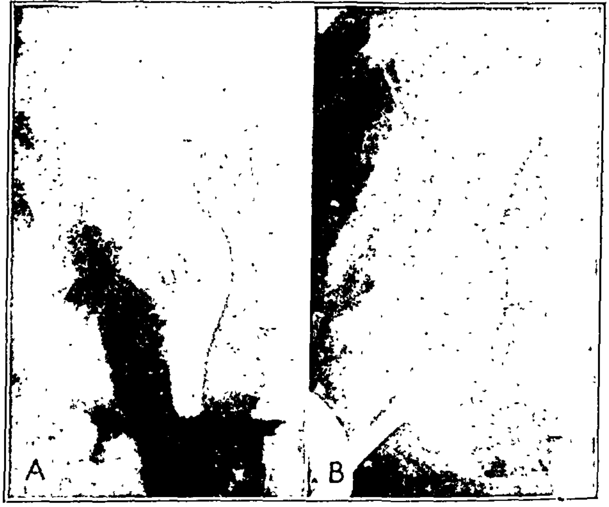

Fig. 2.—A—Postoperative cholangiogram made one month after removal of common duct stone. It illustrates obstructive dilatation of duct system despite use of amyl nitrite. Continued T tube drainage and reexamination in one month were advised. B—Cholangiogram one month later demonstrates patency of common duct and considerably less dilatation of duct system. *Previous obstruction was probably due to residual inflammatory changes which subsided on further drainage.*

COMMENT

Extrahepatic Duct Stones.—In the group with extrahepatic duct stones were 46 patients originally operated on at Cleveland Clinic Hospital for biliary disease. Either all presented a history consistent with a preoperative diagnosis of ductal disease or at operation the findings were such as to demand exploration of the common duct. In all patients the duct was first palpated, then probed and finally irrigated. Catheters were passed proximally into the hepatic ducts, and in every case the common duct was believed to be patent as a probe was passed distally into the duodenum.

Stones were recovered at operation in each one of the 46 patients. Thirty-three had cholelithiasis and choledocholithiasis, while 10 patients had stones only in the gallbladder. In the 3 remaining patients stones were recovered only from the common duct.

Eleven of the 46 (23.9 per cent) required a second

operation for a stone or stones not found at the first exploration. In 1 patient it was necessary to do a third operation before all the stones in the common duct were removed. Our incidence of cases in which stones were not found at first exploration parallels Mixter's incidence.[6d] 26.8 per cent. At the time of the first operation 9 of the 11 had stones in both the gallbladder and the common duct; 1 had stones in the gallbladder only; and 1 had stones in the common duct only. In 10 of the 11 patients the stones in the biliary duct were accurately identified by postoperative cholangiograms which were made within a thirty-four day period. The other patient was reexplored without having had postoperative cholangiography.

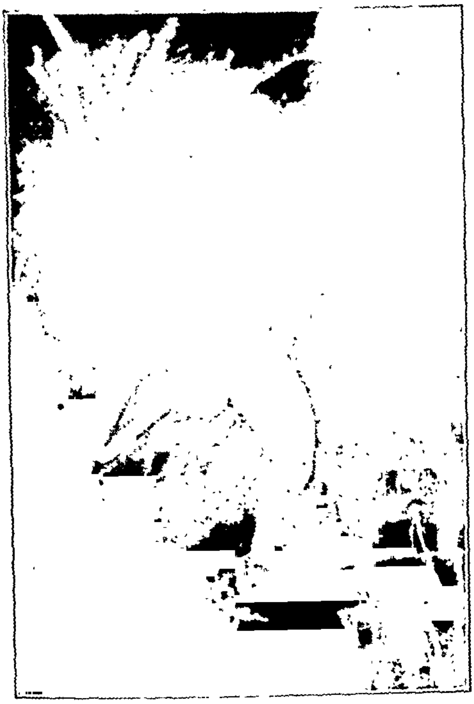

Fig. 3.—Stone found at ampulla as well as pronounced dilatation of duct system despite incomplete obstruction, as indicated by dye in duodenum.

It is our opinion that this interval of time was too short for new intraductal stones to form and that reoperation might have been avoided in all 11 cases if cholangiography had been employed at the time of operation.

Abell[7] adequately explained the surgeons' difficulty when he stated that if many stones are present in the common duct it is not always possible for the surgeon to be sure he has removed them all. In addition he believes that if the gastrohepatic omentum is thickened because of edema and swelling or if the common duct passes directly through pancreatic tissue before entering the duodenum it is practically impossible to determine whether stones are present in the duct by palpation alone. One of our own cases beautifully illustrates this point. A second operation was performed to recover a stone not found at the first operation and later identified in the distal end of the common duct by a postoperative cholangiogram. At the second exploration no stone could be found after careful palpation of the entire common duct, but because of definite cholangiographic evidence, a transduodenal exploration of the common duct was undertaken and an almond-sized stone removed from the ampulla (fig. 3).

In addition to our own 46 patients there were 19 others who had had original biliary operations elsewhere. All of these required a second operation at the Clinic Hospital to remove from the biliary duct stones apparently not found at the first operation. Five of these 19 patients (25.2 per cent) required a third operation before all the stones were removed from the ducts. In 1 of these the stones were lodged in the hepatic ducts. Delayed cholangiography revealed the stones in 4 of these 5 patients. In the fifth patient, who had stones in the hepatic ducts, cholangiography failed to disclose the stones. We attribute this to a previous hepatoduodenostomy because, as will be explained later, it is not always possible to outline the hepatic ducts satisfactorily after this surgical procedure.

So far, immediate cholangiography has been used at this hospital on a proportionately small series of patients, but in none of these has reoperation been required to date. It is rather widely agreed that immediate cholangiography is not infallible in the presence of multiple small stones or gravel or sand, especially when there is no obstruction of the duct.

Extrahepatic Duct Stricture.—Twenty-five patients were referred to the Clinic with obstruction of the biliary tract due to stenosis or stricture of the common duct. Eleven of these patients required more than two operations, and a total of sixty-five surgical procedures were done on the 25 patients. Some type of surgical anastomosis was necessary in each instance to insure free flow of bile into the intestinal tract.

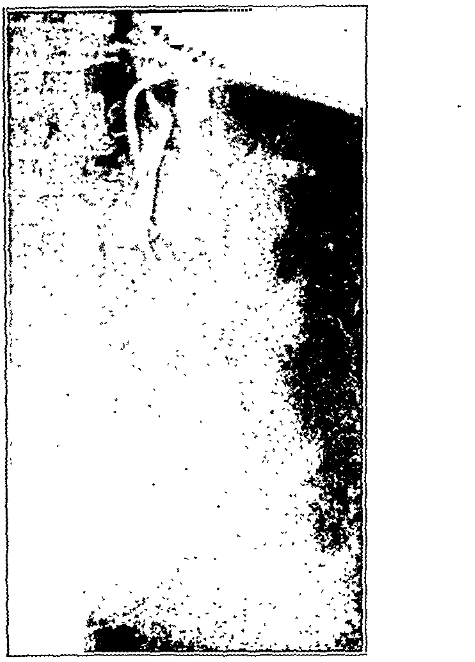

Fig. 4.—*Postoperative cholangiogram demonstrating reconstruction of severed common duct about T tube. Patency of anastomosis indicated by absence of dilatation and presence of dye in small bowel.*

It is frequently difficult to determine by either history or surgical exploration the cause of these strictures. Jaundice with acholic stools was present in 22

of the 25 patients. Eight had the onset of jaundice from a few days to four weeks following the primary operation. The usual story described excessive drainage of bile occurring shortly after operation, persisting for a few days, then diminishing, only to be followed by the appearance of jaundice and acholic stools. In this group transection of the common duct at the first operation was believed to be the most common cause of trouble.

Six of the 25 patients were free of jaundice for one or more years, following the first operation, and 8 others had intermittent attacks of jaundice. In these 14 patients the cause of obstruction is debatable, but conjecture is permissible. Judd[8] was of the opinion that an obliterative inflammation can and does occur in the duct system. Gray,[4] on the other hand, believed that trauma at the first operation was a much more logical explanation of either immediate or delayed obstruction. Recently Cattell[9] reported a series of 123 benign strictures of the biliary ducts, 80 per cent of which were caused by operative injury.

Cholangiography at the time of the second exploration is seldom feasible if the ducts have been cut or traumatized. Either the proximal end of the cut duct retracts into the liver bed, or what remains of the duct is hardly more than a fibrotic cord, making it impossible to inject opaque material. However, if the common duct can be reconstructed over a T tube, injection of dye through the tube will give additional information as to the character and patency of the anastomosis (fig. 4).

Cholangiograms following choledochoduodenostomy or hepatoduodenostomy are primarily of value to show the flow of dye into the duodenum. With such anastomosis the action of the sphincter of Oddi is eliminated, and it is usually impossible to build up sufficient intraductal pressure to visualize completely the hepatic radicles.

SUMMARY

Postoperative cholangiography was 93.3 per cent accurate in demonstrating in the common duct stones not found at previous surgical explorations. Cholangiography at the time of operation can lower the incidence of reoperation for stone or for ductal trauma and prevent stricture due to unrecognized operative trauma. Operative cholangiography in the presence of stricture, stenosis or transection of the common duct may not be feasible. Delayed cholangiography in this group can demonstrate the patency of the newly constructed anastomosis. In all cases, postoperative cholangiography provides the best criteria for discontinuing T tube drainage.

ELECTROENCEPHALOGRAPHIC STUDIES IN POLIOMYELITIS

ALTON GOLDBLOOM, M.D.,
HERBERT JASPER, M.D.
and
HELEN FRIEDMAN BRICKMAN, M.D.

Montreal, Canada

There has been much speculation as to the extent of cerebral involvement in poliomyelitis. Recent pathologic and experimental material has suggested that it is greater than what would be suspected on clinical grounds.

The proportion of cases with frank clinical manifestations of encephalitis is relatively small in most epidemics of poliomyelitis. In those instances, the drowsiness deepening into coma, often profound and prolonged, the tremors and the rigidity, leave no doubt as to the invasion of the brain by the disease process. Involvement of the brain is much less certain in milder clinical pictures, although it has been suspected as an explanation of the unusual emotional states often encountered during the acute stage of poliomyelitis. As for the disturbed behavior which has been known to occur as a late sequel of poliomyelitis, and which is being extensively studied,[1] most explanations have been based on the psychologic trauma of crippling disabilities and prolonged hospitalization. However, the possibility that some of those disturbances may have an organic basis analogous to other postencephalitic states has by no means been excluded, and remains for our further consideration.

In the monkeys inoculated with poliomyelitis virus by Hurst,[2] no part of the central nervous system ever entirely escaped damage. Sabin and Ward[3] demonstrated lesions in the basal ganglions, midbrain and hypothalamus in monkeys with nonparalytic poliomyelitis. Bodian and Howe[4] have demonstrated that in monkeys in whom experimentally produced poliomyelitis was nonparalytic, almost every degree of severity and spread of pathologic change could occur. It is conceivable that this may be true of nonparalytic and nonencephalitic cases among human beings as well. Pathologists have for many years pointed out that poliomyelitis affects the central nervous system in a most diffuse manner[5] and that in human necropsy material there is a disparity between the severity of the lesions found in the brain and the clinical indications of encephalitis.[6] However, cases of severe disease with fatal outcomes are necessarily those on which such observa-

tions were made. Until there are more pathologic studies of cases of nonfatal poliomyelitis in which death was due to an unrelated cause the problem will remain unsettled.

In the meantime, it would seem reasonable to consider whether electroencephalographic analysis of patients with poliomyelitis might serve as a useful extension of our clinical criteria of encephalitic involvement in poliomyelitis.

MATERIAL AND METHODS

Fifty patients who contracted poliomyelitis in the summer and autumn of 1946 were examined electroencephalographically. An effort was made to include as many patients as possible with definite signs of encephalitis: These comprised only 18 per cent of the series. The remainder of the cases were taken at random and included a variety of clinical pictures due to poliomyelitis. Thirty-nine of the 50 patients were under 14 years of age, distributed fairly evenly between the ages of 2 and 13 years. The others ranged in age from 14 to 34 years. These children and the adults were patients at the Children's Memorial Hospital or the Alexandra Hospital,[7] with the exception of 2 whom members of the attending staff of the Children's Memorial Hospital enabled us to include in this series.

A total of sixty-four electroencephalographic examinations were made. Thirty-nine of the patients were examined once, 10 twice, and 2 were examined three times. Fifteen of the patients were examined within three months of the onset of their disease. Eleven of these were reexamined after an interval of five to eight months, the other 4 not being available for reexamination. One patient was examined four months after his disease began and again three months later. Each of the remaining 34 patients had a single electroencephalogram taken between four and eight months after the onset of poliomyelitis.

We were interested in the various clinical manifestations of encephalitis in these patients. Five children were comatose for periods varying from several hours to twenty-five days. In 3 of these, generalized plastic rigidity was an outstanding feature; on disappearing, it left a spastic hemiparesis in its wake, which was indistinguishable in 1 case from that caused by an upper motor neuron lesion. In this latter instance, aphasia was also present. Two of these children exhibited coarse tremors, of a type usually associated with lesions of the basal ganglions. A sixth child was profoundly apathetic and irritable, although retaining consciousness, and showed gross tremors and incoordinate movements. These 6 patients were considered to have had manifestations of severe encephalitis. Three other patients were classified as manifesting moderate encephalitis; 1 young adult was confused and irrational for two days; 1 child wandered from his bed, apparently disorientated, and in addition exhibited occasional coarse tremors; 1 child had a convulsion, and later strolled right out of the hospital.

Lesser degrees of drowsiness, apathy, delirium or irritability, mostly accompanying fever, occurred in 14 patients. These reactions were not more pronounced than what one sees during the acute stage of many infectious diseases in children, though they may well represent a mild encephalitic involvement of some sort. For the purpose of this study these patients were classified as manifesting slight encephalitis. Finally there were 27 patients who manifested no such symptoms at any stage of their disease, and these were classified as showing no apparent clinical signs of encephalitis.

In assessing the problems of behavior and personality in these patients, we had recourse only to information obtained from the case reports and the nursing staff as to behavior during the stay in the hospital, and from the parents or close relatives as to behavior after discharge. (It is hoped to include psychiatric examination of these patients in a long term study of these relationships; this is planned for the near future.) Eleven patients, all children, were reported to have shown moderate or severe personality disorders. (Only 3 of these had much physical disability.) Emotional instability, as shown by a tendency to weep (less commonly to laugh) on slight and quite inadequate provocation, was common to all of these children. This feature has been noted in previous studies. Four were having trouble in school, due, it was thought, to increased difficulty in learning, although in 1 case it was felt that the child could learn as well but at a slower rate than hitherto. All these children were more irritable, some to an extreme degree. Four were reported to have become aggressive. Two had fear fantasies, and one was negativistic. Besides these 11, 9 children showed mildly disturbed behavior. In 7 of these, unwarranted weeping was the chief change. Three had night terrors in addition. One child became unwontedly submissive: 1

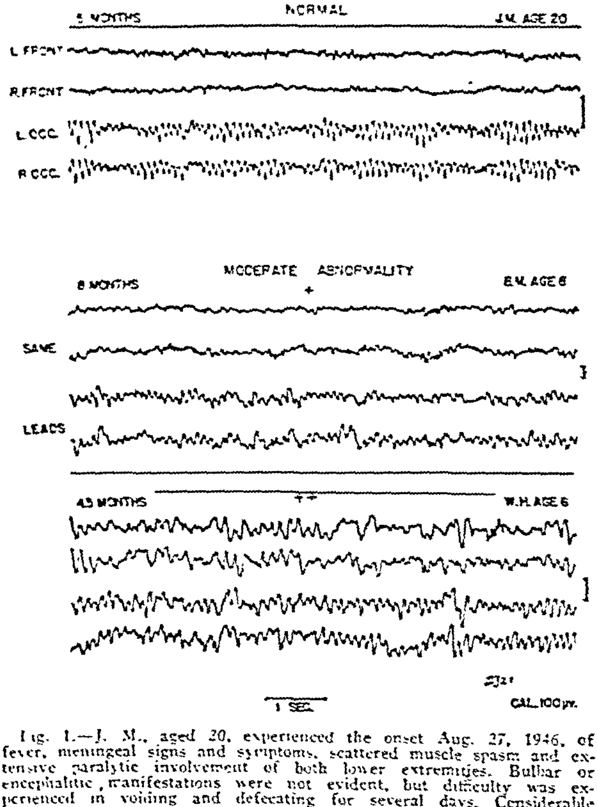

Fig. 1.—J. M., aged 20, experienced the onset Aug. 27, 1946, of fever, meningeal signs and symptoms, scattered muscle spasm and extensive paralytic involvement of both lower extremities. Bulbar or encephalitic manifestations were not evident, but difficulty was experienced in voiding and defecating for several days. Considerable pleocytosis was present, and a positive reaction to the Pandy test in cerebrospinal fluid. There was no personality change. B. M., aged 8, suffered the onset July 27, 1946, of fever, headache and nuchal rigidity. Weakness in left calf and nasal tone of voice developed with deviation to the left of the palate. There was moderate pleocytosis and a positive reaction to the Pandy test in the cerebrospinal fluid. B. M. has been irritable since then and does not maintain previous good standard of school work. W. H., aged 6, experienced the onset Sept. 4, 1946, of fever, headache, vomiting, drowsiness, confusion and finally coma for several days. There was slight meningeal irritation, spotty distribution of muscle spasm and weakness. Generalized clonic movements and plastic rigidity were most pronounced in the right upper limb; there were pleocytosis and positive reaction to the Pandy test in the cerebrospinal fluid; persistent right spastic hemiparesis with gradual improvement; emotional instability during early convalescence with no residual personality disorder.

---

[7] Dr. E. M. Worden granted us permission to examine the records of the poliomyelitis wards at the Alexandra Hospital.

seemed to lose all affective feeling toward his siblings. The remaining 30 patients were reported to exhibit no change in their behavior not easily accounted for (for example, several parents remarked that their children had become spoiled since they had been ill).

In addition to the 50 patients described, 8 children were examined five years after acute poliomyelitis (in 1942) Their protocols were taken at random from the files of the Children's Memorial Hospital. None had a history of pronounced signs of encephalitis, although in 1 child the mother reported unusual drowsiness for four days prior to admission. Questioning the parents with regard to behavior revealed that in 2 behavior difficulties had become sufficiently great to require psychiatric treatment. In 1 other child there was poor emotional adjustment during convalescence, while in the remaining 5 children no significant behavior difficulty was noted. The results of the electroencephalographic examination of this group of patients will be considered separately as a preliminary study of the possible late residual changes.

Electroencephalographic examinations were carried out at the Montreal Neurological Institute with the standard technic used in these laboratories.[8] Records were taken under standard conditions from left and right frontal regions and from left and right occipital regions with the ears as a reference, and also with paired leads on the scalp over frontocentral and parieto-occipital regions on each side. In special instances additional electrodes were placed to localize more precisely some abnormality apparent in the exploratory examination.

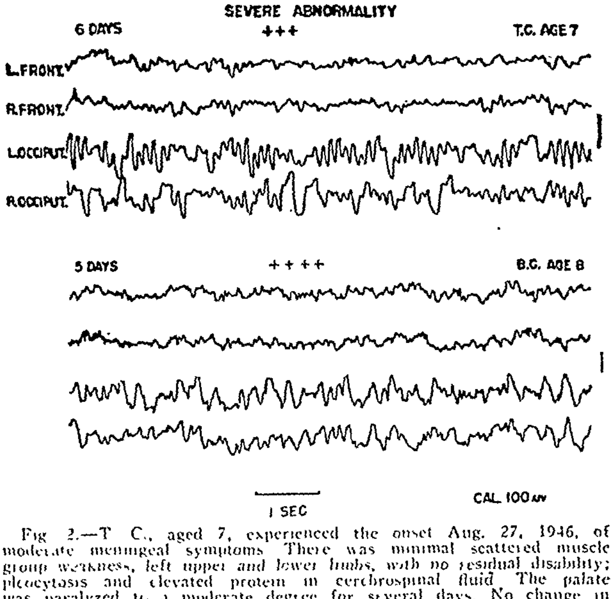

Fig 2.—T C., aged 7, experienced the onset Aug. 27, 1946, of moderate meningeal symptoms There was minimal scattered muscle group weakness, left upper and lower limbs, with no residual disability; pleocytosis and elevated protein in cerebrospinal fluid The palate was paralyzed to a moderate degree for several days. No change in personality occurred B. C., aged 8, experienced the onset Sept 1, 1946, of slight fever, symptoms of meningeal irritation, some drowsiness and slight confusion in first few days There was no evidence of cranial or spinal nerve paralysis. A slight pleocytosis and a positive Pandy reaction in cerebrospinal fluid were present. B C is now emotionally unstable and aggressive, receiving unsatisfactory grades at school

Hyperventilation for two to three minutes was carried out in most cases. In many cases, when the response to hyperventilation was pronounced, 75 Gm. of glucose was administered by mouth and the hyperventilation repeated in twenty to thirty minutes in order to rule out a response to hyperventilation facilitated by low blood sugar.

The electroencephalographic records were interpreted as they were taken by either Dr. Herbert Jasper or Dr. David Daly and the degree of abnormality indicated on an arbitrary scale of 1 to 4 plus (figs. 1 and 2), somewhat similar to that described by Jasper and Kershman for electroencephalograms in patients with head injuries.[9] Special allowance was made for the slower spontaneous rhythms and the greater amount of irregularity normally observed in young children. The normal tendency for children to be more readily affected by hyperventilation was also taken into account in the interpretation of these records. However, when high-voltage slow waves appeared after thirty seconds to one minute of hyperventilation and were repeated after the administration of glucose, it was considered of some significance in the evaluation of the degree of electroencephalographic abnormality. This reaction was considered of more definite significance in children over 10 years of age.

Finally, after the present series was complete all the electroencephalogram records were reviewed by one of us (H. H. J.) and the ratings as to the degree of abnormality reconsidered. It was found that a few of the records had to be reclassified slightly but that in most instances the original classification was retained, and what is more important, the classifications given by Dr. Daly independently were in most instances confirmed exactly by one of us (H. H. J.) in the final review of the records.

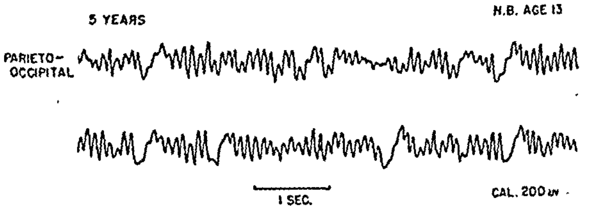

Fig. 3.—Fused alpha activity N. B, aged 15, experienced the onset Aug. 6, 1942, of headache, listlessness and meningeal signs and symptoms. There was paralytic involvement mainly of the right upper limb. Extensive and persistent muscle spasm occurred with development of severe scoliosis; moderate pleocytosis was present and a positive reaction to Pandy test in cerebrospinal fluid N B was a behavior problem during early convalescence with objectionable attention-securing maneuvers. No residual change has occurred.

RESULTS

The form of abnormality consisted chiefly of the replacement of the normal alpha and beta rhythms more or less completely by slow waves of moderate voltage at frequencies from about 6 per second down to as slow as 1 per second in the extreme cases (figs. 1 and 2). In the cases of milder disease the disturbance was frequently limited to a curious irregularity in the parieto-occipital alpha rhythm giving the appearance of the fusion of a number of alpha waves into an irregular slow wave (fig. 3). This "fused alpha" picture was observed to form a part of the abnormality in 26 of the 37 patients with abnormal electroencephalographic records. In the cases of more severe disease the slow wave abnormality appeared diffusely from all head regions but was often particularly prominent when the ears were used as reference electrodes ("monopolar"), which suggests involvement of subcortical cerebral structures. This was confirmed in some instances by means of the "basal lead" placed on the posterior part of the nasopharynx. In a few cases one hemisphere seemed much more involved than the other, and occasionally the abnormality seemed greater from a particular brain area, though in no cases was focal abnormality present without some disturbances in the electrical activity of the rest of the brain. In all cases showing any abnormality whatsoever there was a disturbance in the parieto-occipital alpha rhythm of both hemispheres.

The sudden appearance of slow waves, 3 to 6 per second, of increased voltage during a short period of hyperventilation (one to two minutes) was found in 14 of the 32 patients in whom this test was carried out (fig. 4). In 13 of these 14 positive reactions the patients were under 10 years of age. Only 7 of the 18 patients giving negative reactions were under 10 years of age. The greater proneness of children to electroencephalographic disturbances with hyperventilation is well recognized, so that an evaluation of these reactions in young children following poliomyelitis is difficult. We are of the impression, however, that the reactions observed in this group were more severe and of higher incidence that would be expected in a random sampling of "normal" children in this age group,[10] although the final interpretation of this observation must await further study.

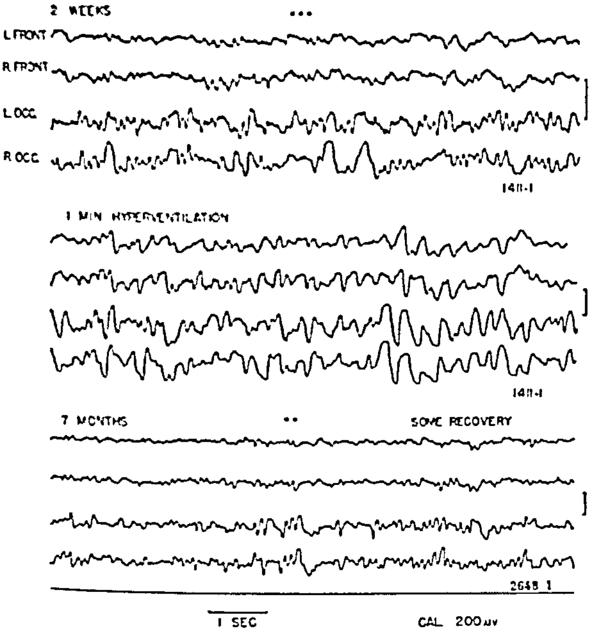

Fig. 4.—M. C., aged 10, had a difficult forceps birth and experienced fainting spells throughout early childhood, usually when fasting or when riding streetcars. There was insidious onset Aug. 9, 1946, of malaise, slight fever, anorexia and vomiting. A few fainting spells, headache and pain in the back and legs preceded a brief tonic convulsion for which she was admitted August 21. She was afebrile and well thereafter, although disorientated on the second day in the hospital. Fasting blood sugar and nonprotein nitrogen levels and roentgenograms of the skull were normal. Protein in cerebrospinal fluid was elevated. Minimal transitory paralysis of the right lower limb, a suggestion of acute encephalopathy in t occurrence of definite poliomyelitis in a a diagnosis of polioencephalitis. There was

Fifteen patients were examined initially during the first three months, including 9 patients examined within five to twenty days of the onset of their illness. Abnormal electroencephalograms were found in all these patients; the abnormalities were considered mild or moderate in 8 cases and severe in 7 cases. Of the 11 patients who were reexamined five to eight months later the electroencephalogram had returned to normal in 4, while definite residual abnormalities (4 moderate and 3 severe) were present in the remaining 7 patients. Examples of patients showing definite recovery in the electroencephalogram are presented in figures 5 and 6.

The incidence of electroencephalographic abnormality in the total group of 50 patients examined within eight months after the onset of poliomyelitis is show in table 1.

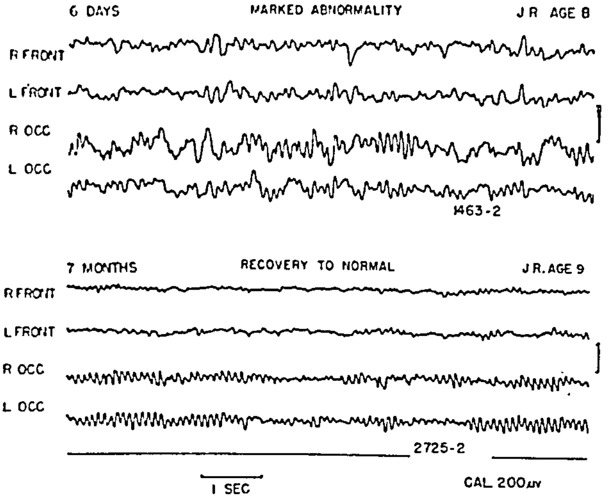

Fig. 5.—J. R., aged 8, experienced the onset Aug. 31, 1946, of fever and severe meningeal irritation, and was delirious for two hours on the third day. Widespread paralysis developed with absent tendon reflexes in right lower limb, as well as persistent spasm and early contracture of right calf muscles. There was pleocytosis and a positive Pandy reaction in cerebrospinal fluid. Since this time J. R. has nightmares and fear fantasies, and weeps on slight provocation.

Normal electroencephalographic records were obtained in only 13 (26 per cent). Of the 74 per cent of cases showing abnormality, in 26 per cent the abnormalities were considered severe and in 48 per cent moderate. There was a clear tendency for more electroencephalographic abnormality to be found in the patients under 14 years of age (82 per cent) as compared with those over 14 years of age (46 per cent). In only 1 of the latter group was the electroencephalographic abnormality considered severe.

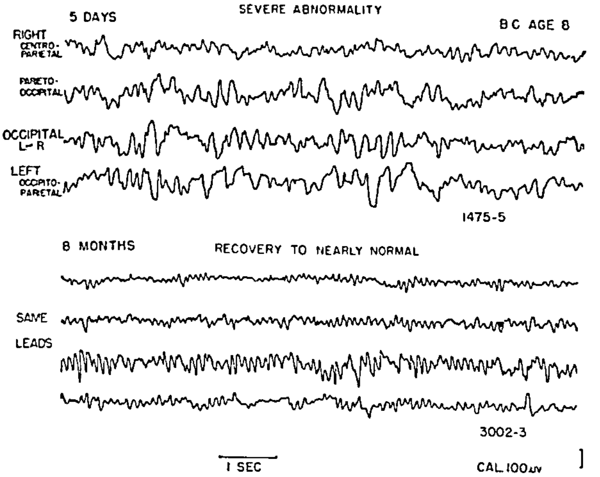

Fig. 6.—B. C., aged 8, experienced the onset Sept. 1, 1946, of slight fever, symptoms of meningeal irritation, some drowsiness and slight confusion in first few days. There was evidence of cranial or spinal nerve paralysis; slight pleocytosis and positive Pandy reaction in cerebrospinal fluid were present. B. C. is now emotionally unstable and aggressive, receiving unsatisfactory grades at school.

In order to eliminate the more acute and more rapidly reversible effects of the disease on the electroencephalogram, results from 46 patients examined between four and eight months after the onset of the illness were considered separately in table 2. There were 30 patients in this group (65 per cent) who showed definite residual abnormality in the electroencephalogram; in 23 it was considered of moderate degree (48 per cent) and in 8 it was considered severe (17 per cent). The importance of age is equally clear in this group, since electroencephalographic abnormality was present in 74 per cent of patients under 14 years of age and in only 36 per cent of those over 14, none of the latter group having abnormality of severe degree.

	Moderate	51.3%	36%	48%
	Total	82.1%	46%	74%
Normal E.E.G.		17.9%	54%	26%

In a further preliminary attempt to ascertain how long these electroencephalographic changes may persist we have examined 8 patients five years after the acute attack of poliomyelitis. In 5 of these patients definite abnormalities were observed in the electroencephalogram, considered of severe degree in 2 and of moderate degree in 3. In addition one of us (H. H. J.) with Dr. Penfield has recently examined a patient with extremely severe residual electroencephalographic abnormality of a diffuse character which resulted from a severe attack of polioencephalomyelitis fifteen years ago. There was residual lower motor neuron paresis of the lower extremities, but the patient was referred to us because of severe and persistent generalized epileptiform seizures which developed fifteen years after the acute encephalitis. There was also a progressive deterioration in personality. This patient presented the most extreme residual of polioencephalitis yet encountered, both with regard to the clinical condition and the changes in the electroencephalogram, but the difference should probably be considered one of degree rather than of kind when compared with the other cases in this series.

TABLE 2.—*Electroencephalograms 4 to 8 Months After Onset of Poliomyelitis*

	Total	6	3	10	17
Normal E.E.G.		0	0	4	10

The relation between the clinical signs of encephalitis and the degree of abnormality in the electroencephalogram was examined (table 3). All of the 9 patients who had been considered to have shown clinical signs of severe moderate encephalitic involvement during the acute stage of their disease were found to have abnormal electroencephalograms (6 moderate and 3 severe). The electroencephalographic records were not taken during the acute stage of the disease, all but one being taken two to six months later. In the 1 case a severe electroencephalographic abnormality was observed two weeks after the onset of the disease, after the acute clinical signs had subsided, and a pronounced electroencephalographic abnormality was still found on reexamination seven months later. Of the 14 patients who showed only mild signs of clinical encephalitis, there were 10 who showed abnormalities in the electroencephalogram (7 moderate and 3 severe). Two of those with severely abnormal electroencephalograms were examined within the first week of the illness so that the changes represented the acute phase of the disease; in the third patient with severe electroencephalographic changes the electroencephalogram was taken five months after the acute onset. Of the 27 patients with no apparent clinical signs of encephalitis there were 17 with abnormal electroencephalograms (12 moderate and 5 severe). Of the 5 patients with severe electroencephalographic changes only 3 were examined within the first three weeks of the disease. There were 15 of the 27 patients with no obvious clinical encephalitis who showed persistent electroencephalographic abnormality between one and eight months following the onset of the disease.

Table 4 summarizes the correlation between the electroencephalographic abnormality and the behavior disturbance following poliomyelitis in our patients. Ten of 11 patients with severe behavior disturbances showed abnormal electroencephalograms, while 6 out of 10 with normal behavior showed abnormal electroencephalograms.

TABLE 4.—*Final Electroencephalograms and Disturbed Behavior Following Poliomyelitis*

		Marked Behavior Disturbance	Mild Behavior Disturbance	Normal Behavior
Patients Examined		11	10	25
Abnormal E.E.G.	Marked	2	2	4
	Moderate	8	4	8
	Total	10	6	12
Normal E.E.G.		1	4	13

The relation of electroencephalographic abnormality to the level of paralytic involvement was considered. Thirty-seven of the 50 patients had evidence of lower motor neuron paralysis. In 9 of these the involvement was confined to the cranial nerves, in 20 to the spinal cord, and in 8 there were both cranial and spinal involvement. The other 13 patients showed no apparent paralysis. Twenty-seven out of 37, or 73 per cent, with paralysis had abnormal electroencephalograms (17 moderate, 10 severe), whereas 9 of 13 (69 per cent) without paralysis had abnormal electroencephalograms (5 moderate, 3 severe). In the 9 patients with paralysis confined to the cranial nerves, 8, or 89 per cent, had abnormal electroencephalograms (5 moderate, 3 severe). In the 20 patients with paralysis confined to the muscles supplied by the spinal nerves, 13, or 65 per cent, had abnormal electroencephalograms (8 moderate, 5 severe). Six of the 8 patients, or 75 per cent, with both cranial and spinal involvement had abnormal electroencephalograms (4 moderate and 2 severe). Although the number of patients is not large enough to permit definite conclusions to be drawn, these figures suggest a tendency for patients with involvement of the cranial nerve to have a higher incidence of electroencephalographic abnormality than patients with spinal nerve paralysis or without any paralytic involvement.

COMMENT

Evaluation of the significance of electroencephalographic abnormality of the diffuse nonspecific form observed in many of the patients in the present study must be made with some caution if these changes are to be definitely attributed to polioencephalitis. Since in no patients were there available electroencephalograms taken prior to this disease, the question of some form of encephalopathy existing prior to the polioencephalitis must be considered. In the first place such factors as hereditary nervous disease, birth difficulty or injury, previous encephalitis of any form or previous severe head injury were not notably prominent in the group of cases studied. In 1 case (M. C.) (fig. 4) there was a history of difficult forceps birth and "fainting spells" prior to the polioencephalitis. There were only 2 other patients in this group whose previous medical history might have had a bearing on this problem; namely, a girl who had been brought to the outpatient clinic for "nervousness" and behavior difficulty and a boy who appeared to have been mentally retarded None had a previous history of encephalitis of any form. Unfortunately, facilities have not been at our disposal for a thorough neuropsychiatric analysis as is being carried out in Denver by Dr. Ebaugh and his associates.[1a] Such a study is planned for the subsequent follow-up of these patients. It can be said at present, however, that there was no evidence available in the previous historiesof all but 2 or 3 of the patients in this series which might have contributed to the electroencephalographic abnormalities observed after their attack of poliomyelitis.

The criteria of electroencephalographic abnormality used in this study were severe. We have ignored minor irregularities, and in the younger children even rather pronounced irregularities, which might be considered of borderline significance in a random sampling of the "normal" population of this age group. Consequently the high incidence of 74 per cent definite electroencephalographic abnormality observed can be reasonably explained only on the basis of some encephalopathy due to the poliomyelitis virus.

The form of electroencephalographic abnormality was also more consistent with an encephalitic etiology,[11] although its diffuse character might have been due to other causes. Except in 1 or 2 cases there was no suggestion of the form of abnormality usually found in patients with idiopathic epilepsy. The peculiar disorder of the parieto-occipital alpha rhythm, termed "fused alpha" (fig. 3) was particularly prominent in this series of cases, although it cannot be considered specific for polioencephalitis. It may represent a disorder in the diencephalic regulating centers for cortical rhythms rather than a specific involvement of the occipital cortex itself, since cortical rhythms often reflect conditions existing in their subcortical projection nuclei.

Finally, the fact that the electroencephalographic abnormality was always most severe (except in 1 patient) if the examination was carried out during the first week of the illness and that definite recovery was observed in records taken several months later, some returning completely to normal (fig. 5), is perhaps the strongest argument in favor of the assumption that the disturbances in the electroencephalogram were, in most instances, a manifestation of the effects of polioencephalitis.

The difference between the incidence of electroencephalographic abnormality in the children and the incidence in the adults of this series is arresting. When Ebaugh and Hoekstra [1] in Denver reported that there was no significant abnormality in, the electroencephalograms of patients who had had poliomyelitis, we were struck by the discrepancy between this finding and our early results, which were disclosing a rather high incidence of abnormality. The Denver investigators had, however, purposely selected patients over 14 years of age in order to facilitate psychiatric examination, whereas we were dealing with patients of a wider age group, and mainly with children. We then analyzed our findings with regard to age (tables 1 and 2). The low incidence of abnormality in the group over 14 was in substantial agreement with the findings in Denver, but the strikingly high incidence of electroencephalographic abnormality in the children of this series is the significant new fact disclosed. It is difficult to explain this selective susceptibility of children to electroencephalographic disturbances following an attack of poliomyelitis.

A close correlation between clinical and electroencephalographic evidence of encephalitis has been demonstrated in one direction at least, inasmuch as all 9 patients with recognizable encephalitis had definitely abnormal electroencephalograms (table 3). In addition, 1 patient with an upper motor neuron lesion, whose clinical picture suggested encephalitis of a more focal character, had electrographic findings consistent with such localization (fig. 7). The situation is somewhat different when one considers the patients with no clinical suggestion of encephalitis, half of whom showed abnormalities in the electroencephalogram (table 3).

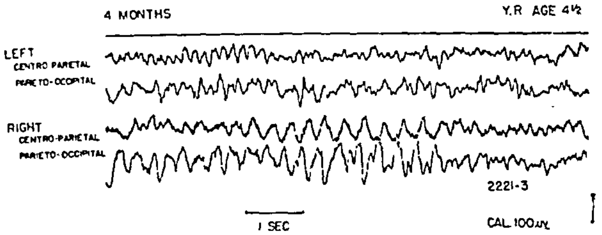

Fig 7.—Y. R., aged 4½, experienced the onset Sept. 6, 1946, of fever, headache and vomiting. Drowsiness and inability to speak preceded the generalized convulsive seizure on the sixth day, after which he was admitted. He remained semicomatose for three weeks. Slight pleocytosis and a slightly positive Pandy reaction in the cerebrospinal fluid were present. Coarse tremor of right arm, right internal strabismus and generalized lead pipe rigidity were replaced later by a spastic hemiplegia with early establishment of flexion contracture deformities. There were residual irritability and slight impairment of speech fluency.

Yet, in the light of both experimental and pathologic demonstration of more extensive cerebral involvement in poliomyelitis than is suggested by the clinical findings, it is tempting to consider that the electroencephalographic changes demonstrated in poliomyelitis represent cerebral disease.

The correlation between the development of disturbed behavior and abnormal electrical activity following poliomyelitis is high, with 10 out of 11 patients with severe behavior disturbances showing abnormal electrograms (table 4). In the 1942 group, all 3 with behavior disturbances had abnormal electroencephalograms. This suggests that there may well be an organic basis of the nature of a subclinical encephalitis underlying some of the severe forms of behavior problems occurring as sequels to poliomyelitis.

There is no correlation between mild personality disorders and electroencephalographic disturbances (table 4). This finding is compatible with the well known complexity of etiologic factors influencing behavior following poliomyelitis. One would not expect to find a close correlation between the electroencephalographic and behavior disorders, since the latter are largely conditioned by environmental situations and the disturbance in cerebral function reflected in the electroencephalogram may not be of a type which affects behavior in this sense.

[11] Lindsley, D. B., and Cutts, K. K.: Clinical and Electroencephalographic Changes in a Child During Recovery from Encephalitis, Arch. Neurol. & Psychiat. **45:** 156-161 (Jan.) 1941 Ross, J. S.: Electroencephalographic Findings During and After Acute Encephalitis, J. Nerv. & Ment. Dis. **102:** 172-182 (Aug.) 1945.

SUMMARY

Abnormalities in the electroencephalogram were found in a large proportion of patients following poliomyelitis. These changes were much more common in children than in adults. Partial or complete recovery was observed in some patients during a period of five to eight months following the acute illness. In others there was evidence of persistent abnormality in the electroencephalogram for at least five to fifteen years. It is concluded that cerebral involvement in poliomyelitis is much more common as judged by changes in the electroencephalogram than would be apparent from clinical observations alone. The possible significance of these findings in relation to disturbances in mentality or behavior was discussed.

ABSTRACT OF DISCUSSION

Dr. M. G. Peterman, Milwaukee: I am glad that Dr. Goldbloom was cautious in his interpretations of the tracings which he presented Ever since Heine first described poliomyelitis in 1840 as a definite, distinct clinical entity, investigators of this disease have considered it polioencephalitis rather than simply poliomyelitis; in fact, since Harbeck and Scheel in 1907 described the changes which they considered typical of this disease, namely, involvement of the meninges and the cerebral cortex, we have come to consider the disease as a generalized infection involving the entire nervous system. Electroencephalographers have considered it impossible to obtain satisfactory tracings in patients with fever. It is well that there was in interval between the acute phase of the disease and the tracing. I believe that it is significant that the authors observed the greatest changes in the first week after the onset of the disease and that most of these "changes" disappeared subsequently. I believe that those "changes" were extraneous and not specific. Poliomyelitis is the same disease in adults as it is in children, and Ebaugh could find questionable changes in only 2 of 16 adults. I feel that there have not been any consistent changes demonstrated here which could be attributed to any specific infectious disease. Assuming that all the patients described had definite poliomyelitis in spite of some of their spastic rigidities, spastic hemiparesis, etc., I see no reason why a certain percentage of them could not have had cerebral dysrhythmia before the poliomyelitis as an entirely unrelated phenomenon. The tracings which I have seen this afternoon have not been convincing. I see variations in tracings every day, particularly in children under 10 years of age. The only specific findings shown here are the slow waves, the cerebral dysrhythmia, which is typical of a convulsive disorder. It is difficult to interpret changes such as those described here. The only positive specific changes which we recognize now are those described originally by Berger and further elaborated on and substantiated by the Gibbs in the various types of epilepsy. Hyperventilation for only two or three minutes is usually not sufficient to produce or precipitate the changes desired in children. The patient labeled "T.C." who had an abnormally slow rhythm could very well have had epilepsy, inasmuch as she had a convulsion or a history of convulsions before she had poliomyelitis, and her sibling could very well have had abnormal changes due also to a congenital cerebral dysrhythmia. I agree with Dr. Goldbloom that this is an extremely interesting study, but I should be loath to draw any conclusions on the changes which he has presented.

Dr. David Bodian, Baltimore: Three features of the pathologic picture of poliomyelitis must be clearly understood before one can make a satisfactory correlation of clinical symptoms, abnormal electroencephalograph findings and the pathologic substrate of both. The first is that all the evidence available shows conclusively that every case of poliomyelitis, human or experimental, exhibits lesions of the brain. The second is that in human poliomyelitis, as well as in most experimental cases, some parts of the brain rarely, if ever, are affected. These include primarily the entire cerebral cortex except for the motor areas, the corpus striatum, except for the globus pallidus, and the cerebellar cortex except for the vermis; in other words, the brain stem as far forward as the hypothalamus and thalamus bears the brunt of the cerebral pathologic changes in poliomyelitis. The third important generality is that great variation occurs in the severity of the pathologic involvement of most centers of the central nervous system, but the same centers are generally involved in greater or lesser degree in almost all cases. It is interesting that pathologic studies and electroencephalographic studies seem to agree in suggesting the brain stem as the primary source of electroencephalographic abnormalities. For example, the paper under discussion suggests a tendency for patients with involvement of the cranial nerve to have a higher incidence of electroencephalographic abnormality than patients with spinal or nonparalytic involvement. Our cases show a definite correlation of severe involvement of the cranial nerve with severe involvement of other brain stem centers, but not with unusual cortical abnormality. I am not competent to judge critically the evidence from the electroencephalograph regarding the organic basis of personality changes in poliomyelitis. Such changes can hardly be the result of damage to the cerebral cortex, since lesions are conspicuously absent from most of the cortex. Severe lesions are present, however, in the hypothalamus and thalamus in some of our cases, and in these cases general involvement of the brain stem is severe. If injury to these centers can contribute to emotional disturbances, then perhaps one can account for a correlation of electroencephalographic abnormality with severe behavior disturbances. I am glad to note, however, that the authors point out that complex factors must influence any behavior changes which follow poliomyelitis infection. Although the younger age group in general showed a tendency toward greater intensity of pathologic reaction in the brain stem, I am not inclined to attribute great significance to such a finding in our relatively small series of cases.

Dr. J. A. Toomey, Cleveland: In 1925 we demonstrated (Toomey, J. A. and Lipson, H. A., Poliomyelitis: Report of a Case, *Am. J. Dis. Child.*, 41:1389, 1931) that severe pathologic changes, present in this disease at times, often bore no parallel relation to the symptoms exhibited. Notwithstanding massive destruction and that but a few of the anterior horn nerve cells were present and that gliosis was found at autopsy, during life the use of the muscles of both arms and legs was only slightly modified in the left gastrocnemius in this case. This was the first demonstration in the human being, to my knowledge, that extensive pathologic changes may be unaccompanied by clinical symptoms and, occurring as it did in a patient who recovered from poliomyelitis but who died from another disease but a short time afterward, it presented irrefutable evidence as to the truth of this assertion. The motor function may not be impaired—the muscles may even perhaps be hyperactive—and the patient merely show signs of encephalitis, though it is more common for him to have encephalitis together with weak or paralyzed muscles. Encephalitis unaccompanied by complicating involvements of the bulb or other part of brain or cord occurs. I have even seen proven cases of involvement of basal nuclei with subsequent recovery from this disease. I have had many patients with complicating encephalitic signs, but in over twenty-five years of experience with this disease I have never seen any modification of the higher faculties should the patient recover. Were he normal in intelligence before, he was that afterward; if a moron before, a moron afterward. I do not doubt that electroencephalographic changes occur; they occur with any infectious disease. Such personality changes that occur—and they do occur, as the speaker states—were the results of the patient's psychic reaction to crippling disabilities, and to environmental difficulties. Although the significance of electroencephalographic changes must be interpreted with caution, and that some form of encephalopathy might have existed prior to the disease, as the authors state, it would be stretching a point to conclude that all these patients had some prior trouble. I would agree with the reasoning of the essayists and would also be tempted to consider the electroencephalographic changes evidence of cerebral disease, but I still wonder whether the postdisease behavior problems are due to things other than cerebritis. I do not see how one can tell without further study and data. The variance between young and old is intriguing.

DR. MEYER A. PERLSTEIN, Chicago: In the interpretation of electroencephalograms in children there are many pitfalls to be avoided. One does see "abnormal" patterns (i.e., as compared to adult patterns) more frequently in children; in other words, the abnormal for adults is normal for children, and the younger the child, the more "abnormal" appearing its normal electroencephalographic patterns are. Of course, Dr. Goldbloom has fortified himself with an experienced electroencephalographer, so that we cannot criticize the interpretations of the tracings shown. Apparently the controls are the patients themselves. And if it is a fact that the waves and rhythms classified as "abnormal" by Dr. Goldbloom disappeared after four, five or six or eight months, then we might assume that they probably were normal before the onset of the disease. However, since such transitory abnormalities in the electroencephalogram may follow any generalized infection, it is questionable that there is anything specific about the changes following poliomyelitis. It is also doubtful that the behavior disturbance can be due to anything organic, because if it were so one would expect to get more such disturbances in bulbar forms or involvements of the cranial nerve than in the spinal forms. To the contrary, I have seen the greatest disturbance in behavior where the crippling was greatest. In other words, it was definitely functional, secondary to the degree of motor disability and not to the site of lesion. Likewise, one might say that the obesity that often occurs in these children following the disease might be on an organic encephalitic basis. However, here too the obesity seems to occur primarily in those who have involvement in the legs and cannot get around and not in those who have had bulbar or upper extremity involvement. We have done electroencephalograms in 15 of our last series of cases of poliomyelitis, and these were done and interpreted by Dr. Gibbs in Chicago. We found that all of our cases showed normal electroencephalograms except 1. This happened to be in a child aged 15, who showed a paroxysmal pattern typical of petit mal. These abnormalities were not most prominent in the occipital region, as has been described here today. We feel that this child had petit mal which was clinically not evident, but in no way related to her poliomyelitis. The fact that we do not find electroencephalographic abnormalities following poliomyelitis and that Dr. Goldbloom does find them does not necessarily mean that we are in disagreement. It may only signify that there may be different types of epidemics and that in some epidemics there may be more involvement of the cortical areas, or of the subcortical areas, which may involve by their connections the patterns in the cortical area.

DR. ALTON GOLDBLOOM, Montreal, Canada: It is unfortunate, perhaps, that Dr. Jasper and other members of his staff are not here to discuss the criticisms with reference to the interpretation of the electroencephalograms. I can only say that these interpretations were made not only by Dr. Jasper but were independently made, and critically, in accordance with the most severe criteria, by other members of his staff, who came to identical conclusions with reference to their interpretations. It is our intention to continue further investigation to see whether this is a constant phenomenon in poliomyelitis, to see whether it is merely a phenomenon of this particular epidemic, as Dr. Perlstein suggested, and which we considered, and to see whether again in a larger number, as large a number of patients as we can accumulate, there are more easily discoverable changes in behavior which perhaps can be attributed to changes in cerebral pathology as a result of the disease.

TEMPORAL ARTERITIS

Relief of Headache by Injection of Procaine Hydrochoride

A. M. ROBERTS, M.D.†
and
JOHN MARTIN ASKEY, M.D.
Los Angeles

Temporal arteritis[1] is a condition poorly understood, with an unknown etiology, a variable course and an unsatisfactory treatment. The term is a misnomer in that it is now believed to be part of a generalized cranial arteritis.[2] Severe headache is one of the most serious manifestations and often requires opiates for relief for a longer period of time than is desirable. Relief has occurred in many instances following the removal of a segment of the artery, done primarily to obtain a biopsy specimen. Hoyt[3] said, "From a practical standpoint, the most effective treatment seems to be the removal of a segment of the temporal artery." It was felt that this was due to interruption of the periarterial sensory pain fibers and suggested to one of us (A. M. R.) the use of a procaine hydrochloride block of the sympathetic nerve fibers passing along the vessels. The result in 4 instances has been immediate and striking in the relief of pain. Inasmuch as the pain in many instances is prolonged for many weeks or months (the figure), a simple means for relief of the pain is gratifying.

Showing the facies of pain due to constant headache.

REPORT OF CASES

CASE 1.—Mrs. H. L. B., aged 59, was first seen Oct. 21, 1941 in the office. She had been sick for three weeks with an illness diagnosed as "flu." A headache first developed over the top of the head, but in the last week it had become localized on the right side. She lost her appetite and felt tired. The blood pressure was 130 systolic and 80 diastolic; the blood hemoglobin 9.1 Gm. per hundred cubic centimeters; erythrocytes 5,400,000, and leukocytes 8,350, with a normal differential count. Urinalysis (uncatheterized) revealed 8 to 10 pus cells and a few erythrocytes. Her sinuses were examined and considered irrelevant as a cause for her headache. An electrocardiogram revealed left axis deviation but no other significant findings. A week later, October 28, she complained of a constant right-sided headache which never entirely disappeared. She became progressively weaker and was forced to stay in bed. She lost her appetite, lost weight, and complained bitterly of the constant headache, now bilateral but worse on the right side. She took 1 grain (60 mg.) of

codeine several times daily for only partial relief. About November 15, the true nature of the condition was suspected. Both temporal arteries were found to be firm cords with exquisite tenderness. One to 2 cc. of procaine hydrochloride was injected around the right temporal artery. This produced relief within two or three minutes. She said that this gave the only relief from the headache that she had had since it began. After the injection, the arteries became soft to the touch, apparently due to prompt vasodilation. The subjective improvement was remarkable. The relief was complete until the following day, when there was a slight return of pain. Injection was made several times with almost complete relief of the surface pain. Injections were also made over the occipital arteries, where there were two points of tenderness. Some headache persisted, however, but not the severe surface headaches which she had had. She described it as a deep intracranial headache not as severe as the peripheral pain but persistent and annoying. On December 12 she was admitted to St. Vincent's Hospital. It was thought that injection of the stellate ganglion might produce vasodilation of any intracerebral arteries which were vasospastic and possibly relieve the headache as had the injection around the temporal arteries. The blood on admission showed 11.6 Gm. of hemoglobin and 3,058,000 erythrocytes. On December 13, 20 cc. of 1 per cent "intracaine" (B-diethylaminoethyl-p-ethoxybenzoate hydrochloride) was injected into the vicinity of the stellate ganglion. Moderate Horner's syndrome was obtained with complete relief of the headache. There was some return in a few days and the injection was repeated. She left the hospital December 21, feeling much better, and since then she has had no return of the headache.

Four Instances of Temporal Arteritis Relieved by Injections of Procaine Hydrochloride

				Arteries Involved					
Case	Age	Condition Before	Fever	Temporal	Occipital	Orbital	Supraorbital	Intracranial	Treatment and Outcome
1	59	Virus infection	+	+	+	0	0	+	Arteritis 6 weeks after onset of fever; 4 periarterial and 2 stellate ganglion injections of 1% procaine gave complete relief
2	25	Acute infection of respiratory tract	0	+	0	0	0	0	Arteritis 4 weeks after headache; complete relief from one periarterial injection of 1% procaine hydrochloride
3	66	Acute infection of respiratory tract	+	+	+	0	0	0	Arteritis 8 weeks after fever; periarterial injection of 1% procaine hydrochloride gave complete relief; recurrence, re-injection, relief
4	75	Acute infection of respiratory tract	+	+	+	0	0	0	Negro; temporal swelling, tenderness for 3 months; complete lasting relief after 3 daily periarterial injections of 1% procaine hydrochloride

Case 2.—Mrs. W. P., aged 25, was first seen at the office March 3, 1942 complaining of a unilateral temporal headache. Her mother had had migraine headaches. The headache had developed February 20 and had followed an attack of severe sore throat diagnosed as acute laryngitis by a physician. She stayed in bed a week, was extremely nervous and said that the headaches were "terrible." The scalp was sore and the headache was always on the right side. She had had one-sided headaches since early youth and, because her mother had a history of sick headache, the diagnosis on the first visit was that of migraine. Temporal arteritis was not suspected. She was given tablets of codeine compound on March 18. She said that her headaches were slightly relieved for about two hours after taking the tablets but that they remained continuous. On March 24, over one month after the onset of the headache, there was found "definite localized tenderness over the right temporal artery." The headache was continuous unless she took the pills every two hours. The tissue around the temporal artery was injected with 1 per cent procaine hydrochloride. Following the injection, there was noticeable relaxation of the artery to the touch and loss of tenderness. Before the injection, the artery could be felt as a firm cord without overlying changes in the color of the skin. There was immediate relief of the headache after the injection. On March 26, the headache had not returned. It was the first relief that she had had since February 20, and the tenderness was gone over the temporal artery. On March 31, she reported no further headache. She had had it continuously from the time she awakened until she fell asleep prior to this relief. She was apparently relieved completely of her headache after one injection. The nausea and loss of appetite that she had had at the time of the headache were gone. She has had no further trouble.

Case 3.—Mr. J. M. M., aged 66, was first seen May 4, 1942 complaining of sharp pain in his forehead and the temples which had developed a month before. Two weeks prior to the development of the headache, he had had a virus bronchitis with general weakness, cough and fever, from which he recovered slowly. Physical examination showed a blood pressure of 106 systolic and 64 diastolic, and a pulse rate of 66. He appeared anemic and the pharynx was slightly inflamed. The blood count showed 9.4 Gm. of hemoglobin, 3,600,000 erythrocytes and 11,250 leukocytes with a normal differential count. Acute temporal arteritis was not suspected. He was given ½ grain (30 mg.) of codeine for the headache. He continued to lose weight and the headache persisted. On May 18, 1943 he was admitted to St. Vincent's Hospital. On May 19, the true condition was suspected. A note then read, "The patient had had a bilateral temporal headache for several months with a dull pulsating pain, at times sharp and stabbing. Examination reveals hard, apparently spastic, temporal arteries with localized tenderness."

A diagnosis of cranial arteritis was made. Injection of both periarterial areas relieved the headache markedly. The patient said it was "like lifting a ton off of my head." That night he slept well for the first time in weeks. The next morning there was only a residual ache, not the throbbing pain. The temporal arteries were not tender and were relaxed. By May 24 the tenderness was all gone. On May 26 there was no return of the temporal headache, but he now complained of tenderness in the left occipital area. An area there was felt pulsating and tender and was injected with 2 cc. of 1 per cent procaine hydrochloride with complete relief. On May 29, there was slight return of tenderness at the left temporal artery. One cubic centimeter of procaine hydrochloride was again injected with immediate relief. It was necessary to make injections over the temporal arteries twice more. Each recurrence of headache was much less severe, however, and was immediately relieved by the injection.

Case 4.—Mrs. A. G., aged 75, a Negro, was admitted to the hospital May 12, 1942, complaining of severe, sharp, shooting pains in the head for three months. Three months before she had had a severe cold with rhinitis and bronchitis. Three weeks later, pain and swelling developed in both temporal areas. On admission, her temperature was 100 F., her pulse rate 100 and her blood pressure 160 systolic and 95 diastolic. On examination, there was swelling in both temples, which were tender, pulsating and nodular. A harsh rasping apical systolic murmur was audible. On May 15, three days after admission, 1 per cent solution of procaine hydrochloride was injected around both temporal arteries with pronounced relief. There was slight return of tenderness and pain, so the following two days procaine hydrochloride was injected over both temporal arteries. Because of the tender left occipital artery, on May 17 an injection was also made on the left side. There was complete relief of her headache. On May 22, a genitourinary infection developed for which sulfadiazine was administered;

this relieved her in a few days. On June 2 all evidence of the arteritis was gone. There was no swelling or tenderness. On June 29 she was dismissed.

COMMENT

The immediate relief of the headache by the injection, with a simultaneous change from hardened, tortuous vessels to soft relaxed ones, suggests an acute vasospastic condition. The occurrence of the condition in a woman aged 25 suggests this etiology rather than that it is a concomitant feature of degenerative arterial changes, the usual belief.

Meyers and Lord[4] recently reported the condition in a woman aged 22 years. The development of the arteritis in these 4 instances following acute infections is also evidence of an infectious origin. Although relief of the headache can be obtained by removal of a segment or excision of the artery, there often is multiple involvement of cranial arteries, obviating such treatment. Multiple injections of procaine hydrochloride, however, are feasible and simple.

SUMMARY

Four instances of cranial arteritis involving chiefly the temporal arteries are described. The headaches were gratifyingly relieved by periarterial injections of procaine hydrachloride. This simple procedure is recommended for control of the pain.

ADDENDUM

Since this article was prepared, an article by Dr. S.B. Nadler entitled "Paroxysmal Temporal Headache", which appeared in the September 29, 1945 issue of THE JOURNAL, has been called to our attention. He obtained relief in paroxysmal temporal headaches of the type relieved by pressure over the temporal artery by injecting procaine hydrochloride. This condition is of course different from temporal arteritis. Relief by procaine was considered an indication for ligation and section of the affected temporal artery. In a letter to THE JOURNAL, December 8, 1945, Dr. D.F. Newman of West Palm Beach reported relief by injection alone. Injection of procaine therefore appears to be of value in several types of headaches.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following statement.

Austin Smith, M.D., *Secretary*.

"TEROPTERIN " AND "DIOPTERIN " IN THE TREATMENT OF CANCER

Recent newspaper and periodical publicity regarding "teropterin" stemming from a report by Farber and his co-workers[1] has again raised the hopes of many sufferers from cancer that a "cure" for this disease has been found. Because of the inquiries received by the Council on Pharmacy and Chemistry, the existing evidence regarding the actions of "teropterin" and an allied derivative, "diopterin" is here reviewed.

Chemically, both "teropterin" and "diopterin" are closely related to folic acid (pteroylmonoglutamic acid); "teropterin" is pteroyltriglumatic acid, and "diopterin" is pteroyldiglutamic acid. Leuchtenberger and his associates[2] observed that "folic acid concentrate" and crystalline Lactobacillus casei factor inhibited tumor growth in mice with transplanted sarcoma 180. In another publication[3] these authors reported inhibition of spontaneous mammary cancer in mice with folic acid.

Farber and his co-workers[1] published the first clinical report on the use of "teropterin" and "diopterin" in the treatment of human cancer. They administered these preparations to 90 patients with terminal cancer and noted in some instances a subjective feeling of improvement on the part of the patients and a diminution in pain. No definite beneficial action on the tumors was reported. The authors were chiefly concerned with reporting lack of toxicity due to the drug and noting the subjective effects.

Klainer[4] has reported a case of metastatic adenocarcinoma of the breast treated with "teropterin," but he stated that the reported improvement in the metastatic lesions could not be ascribed to "teropterin," because the patient was also subjected to oophorectomy and injections of testosterone propionate, both of which are known to produce favorable effects on such metastatic lesions.

Lehv, Wright, Weintraub and Arons[5] have described the results of administration of "teropterin" to 20 patients with cancer. These patients were treated for from one to three months with "teropterin" exclusively. Of the objective changes observed, the only one of significance was the tendency to reduction of abnormally high alkaline and acid phosphatase values. Subjectively, relief from pain was observed in most of the patients, and in several instances opiates could be reduced or eliminated entirely. The patients reported a sense of well-being and a state of mental alertness. Five of the patients had died at the time the report was prepared. No objective changes in the malignant lesions were reported.

Meyer[6] has reported that in 7 patients with chronic lymphocytic leukemia, 2 with chronic myeloid leukemia, 2 with multiple myeloma and 1 with acute lymphoblastic leukemia treated for four to ten weeks with "teropterin," no alteration in the blood picture was noted, although some relief from pain and better appetite were recorded.

News stories which have appeared have hinted at possibilities far beyond those set forth in the recorded observations of these investigators. Since it appeared that not all of the available information had yet been published, the manufacturer of these folic acid derivatives was asked if he had information which could be made available to the Council for review. The firm furnished such information, and part of this report is based on data so obtained.

Both "diopterin" and "teropterin" were distributed to at least two hundred and twenty-five investigators, many of whom have reported on only 1 or 2 cases. Data on 154 patients treated with "teropterin" and on 121 patients treated with "teropterin" and "diopterin" which have been furnished the Council form the basis of this report. Since, on the basis of the present available data, there is no significant difference in the results of "teropterin" medication as compared with "diopterin" medication, the results will be combined in this report. It is stated that in 31.6 per cent (87 cases) general objective improvement was noted by the attending physician. Unfortunately, many physicians did not record what constituted "general objective improvement" and it is possible that some of this may have been wishful thinking, particularly in view of the fact that several of the patients reported to have "general objective improvement" died within a few weeks.

[4] Klainer, M. J.: Tr. New York Acad. Sc., 10:71, 1948.

[5] Lehv, S. P., Wright, L. T.; Weintraub, S., and Arons, O.: Tr. New York Acad. Sc., 10:75, 1948.

[6] Meyer, L. M.: Tr. New York Acad. Sc., 10:99, 1948.

Certain objective changes in the patient's condition were reported, however, and among these were changes in appetite, weight and anemia. Improved appetite was seen in 31 per cent of the patients, gain in weight in 14.5 per cent, loss of weight in 30.9 per cent, improvement in anemia in 5.1 per cent and increased anemia in 4.7 per cent. It would not be surprising to see some correction of anemia in view of the close relationship of these compounds to folic acid. That more patients failed to improve may be due to two factors: severity of the disease and short duration of medication. The improvement in appetite may, in many instances, be due to psychic suggestion and may be more apparent than real, as suggested by the fact that far fewer patients showed a measurable gain in weight. It should be remembered, however, that many patients with cancer have prodigious appetites but fail to gain weight.

Emphasis has been laid on the reported analgesic action of "diopterin" and "teropterin." If these drugs have a significant analgesic action, much of the reported subjective improvement in patients may be attributable to this effect; of the patients in whom pain was a significant factor, 38 per cent obtained some relief. In this connection, "teropterin" appeared to be significantly superior to "diopterin," since approximately 50 per cent of those receiving "teropterin" reported relief from pain as against 23 per cent receiving "diopterin." Some of the reported relief may have been of psychic origin, but there is little doubt that much of it was real since many of the patients receiving opiates were maintained comfortably on greatly reduced dosage or with complete withdrawal of other analgesic medication. It should be pointed out, however, that relief from pain in 50 per cent of the patients is far inferior to the percentage of relief seen following the administration of adequate doses of the opiates alone or in conjunction with other potent analgesics. On the other hand, "teropterin" may offer advantages because of the absence of side reactions and lack of hypnotic or sedative effects.

Of greatest interest are the reported actions of these compounds on the tumors and their metastases. Of significance, therefore, is the observation that in 81.1 per cent of the patients, no change was noted in either the primary tumor or the metastatic lesions. In 13.1 per cent, regression of the lesions was reported. However, it should be noted that many of these patients were receiving or had received other forms of therapy such as roentgen rays or radium, and it is not possible to attribute the regression to the drug. In other cases, the criteria for determining regression were not stated, or the location of the lesions did not permit an accurate estimation of changes in size. In the few cases which have come to autopsy, no significant effects on the tumor which could be attributed to the drug have been noted.

It is perhaps too early to conclude that either "teropterin" or "diopterin" has an action or, on the other hand, is ineffective in cancer. Too few cases have been observed, and the study period has seldom been more than a few months, the majority of those on whom information is available receiving less than eight weeks' treatment and observation. Certainly, no critical appraisal of the effects of an agent in cancer can be made in such a brief period; five years is the usually accepted required period of observation.

In view of the lack of conclusive evidence contained in the data reported to date with these compounds, the Council believes it advisable to emphasize again the need for carefully examining publicity on the results of medical research that has been written for public interest and thus designed to have news appeal. In the minds of many physicians as well as members of the general public the impression has been created that "teropterin" has been shown to have a definite anticarcinogenic effect. The facts available do not yet support this view; even if the actions of the drug had been proved to be more dramatic than those reported here, much more critical investigative work would seem necessary before hope for a new lead to a cure can be raised.

The Council also believes that some consideration should be given to the manner in which new agents believed to be useful in the treatment of cancer are investigated. The indiscriminate distribution of such drugs to physicians regardless of the facilities with which they have to work and their competence in the particular field under investigation actually retards scientific progress, is wasteful of material and is not productive of valuable information. The investigation of new remedies should be entrusted to those who are competent by training and experience to conduct critical clinical trials, who have facilities adequate to study the patients receiving the preparation and who will, in a reasonable time, treat sufficient numbers from which statistically valid data may be obtained. Frequently, a manufacturer who is still studying the possibilities of a new drug is besieged with requests for it when the first favorable report appears. This creates an awkward situation: The manufacturer may not wish to risk offending the inquiring physician by refusing the drug, but he knows that if the product fails to elicit the desired response he may be blamed; and yet he is also blamed if he refuses the drug. The only solution is for the medical profession to wait until the product has been proved safe and efficacious and for the manufacturer to stand steadfast in his refusal to give it to any but qualified investigators. In the meantime, the manufacturer has been distributing pamphlets by mail and at exhibits in medical, hospital and nurses' conventions.

The Therapeutic Trials Committee has as one of its functions the arrangement of clinical trials of new agents. The work of this Committee in organizing a collaborative study on androgens and estrogens in mammary cancer already is setting a pattern for investigations of this type. Such investigations, while time consuming, are not as time consuming as piecemeal investigation, and, furthermore, are so exhaustive because of collaboration by experts that the problems and solutions are clearly defined at the end of the investigation.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

CETYL PYRIDINIUM CHLORIDE.—Ceepryn-Merrell.—The monohydrate of the quaternary salt of pyridine and cetyl chloride.—C H ClNO. M. W. 357.99

Actions and Uses.—Cetyl pyridinium chloride, a quaternary ammonium salt, is a cationic detergent that possesses useful surface active as well as antiseptic properties. It is employed in aqueous solution or tincture in appropriate dilutions for topical application in the preoperative disinfection of the intact skin and the prophylactic antisepsis of superficial minor wounds. It is also useful by topical application or irrigation for therapeutic disinfection of accessible mucous membranes and more extensive wounds or infections of the underlying tissues. It may also be used to preserve sterility of instruments during storage.

Cetyl pyridinium chloride is subject to the shortcomings of other cationic detergents employed as germicides in that its action is opposed by anionic detergents such as ordinary soap, may be reduced in the presence of serum and tissue fluids and is not reliable against clostridial spores.

Dosage.—For preoperative preparation of the intact skin, a 1:100 aqueous solution may be used alone for scrubbing for a period of five to ten minutes; when the conventional soap-alcohol-ether-germicide method is to be employed, 1:500 or 1:1,000 tincture dilutions may be used as the germicide if soap is thoroughly removed before application. Similar dilutions of the tincture or a 1:1,000 aqueous solution may be used for topical application to minor lacerations and abrasions. For disinfection of delicate mucous membranes or extensive areas of exposed tissue, from 1:5,000 to 1:10,000 solutions should be used.

Tests and Standards.—

Cetyl pyridinium chloride occurs as a white powder possessing a slight odor. It melts within the range 77 to 83 C. It is very soluble in water, alcohol and chloroform and only slightly soluble in benzene and ether. The pH of a 1 per cent aqueous solution is 6 to 7 as determined by the use of indicators (glass electrode instruments give variable results). The surface tension at 25 C. of a 0.1 per cent aqueous solution is about a 1 per cent aqueous solution, about 41.40; and a 10 per cent aqueous solution, 38.15

Dissolve 0.1 Gm. of cetyl pyridinium chloride in 50 cc. of water. Add 1 cc. of silver nitrate solution to a 5 cc. portion of the solution: a white precipitate forms, which is soluble in strong ammonia solution.

Heat gently about 0.25 Gm. of cetyl pyridinium chloride contained in a test tube until the substance melts and a brown color develops: the odor of pyridine is readily detected.

Add 5 cc. of about one hundredth molar potassium ferricyanide to 5 cc. of the cetyl pyridinium chloride solution: a yellow precipitate forms. Add 1 cc. of a saturated potassium thiocyanate solution to a 1 cc. portion of the cetyl pyridinium chloride solution: a white gelatinous precipitate forms. Add 1 cc. of saturated picric acid solution to 1 cc. of the cetyl pyridinium chloride solution: a yellow precipitate forms.

Weigh, accurately, about 0.5 Gm. of cetyl pyridinium chloride. Dry to constant weight in a vacuum over phosphorous pentoxide: the loss in weight is not less than 4.5 per cent and not more than 5.5 per cent. Ash the dried sample: the weight of the residue is not more than 0.2 per cent.

Weigh, accurately, about 0.25 Gm. of cetyl pyridinium chloride. Transfer to a 100 cc. volumetric flask. Add 5 cc. of buffer solution (260 Gm. of sodium acetate and 250 cc. of 36 per cent acetic acid, mixed with water to make 1 liter). Add 50 cc. of one hundredth molar potassium ferricyanide. Dilute to the mark with water, mix, allow to stand one hour and filter, discarding the first 15 cc. of the filtrate. Add 5 cc. of 10 per cent potassium iodide solution to a 50 cc. aliquot of the filtrate in an iodine flask. Add 10 cc. of hydrochloric acid and allow to stand for one minute. Add 10 cc. of 10 per cent zinc sulfate solution and titrate with one hundredth normal sodium thiosulfate, using starch T.S. near the end of the titration. Each 1 cc. of one hundredth normal sodium thiosulfate is equivalent to 0.01074 Gm. of cetyl pyridinium chloride monohydrate: the cetyl pyridinium chloride monohydrate content is not less than 97 per cent or more than 103 per cent.

WM. S. MERRELL CO., CINCINNATI

Solution Ceepryn 10 per Cent Concentrated: 180 cc. and 3.84 liter bottles. An aqueous solution containing 10 Gm. per hundred cubic centimeters of cetyl pyridinium chloride and 8 Gm. per hundred cubic centimeters of monobasic sodium phosphate for the preparation of solutions and tinctures for external use.

Tincture Ceepryn 1:200 (Tinted): 120 cc., 480 cc. and 3.84 liter bottles. Contains 0.5 per cent of cetyl pyridinium chloride in a tincture medium of 50 per cent ethyl alcohol by volume and 10 per cent acetone by volume.

Tincture Ceepryn 1:500 (Tinted or Untinted): 120 cc., 480 cc. and 3.84 liter bottles. Contains 0.2 per cent of cetyl pyridinium chloride in a tincture medium of 50 per cent ethyl alcohol by volume and 10 per cent acetone by volume.

Tincture Ceepryn 1:1,000 (Tinted): 120 cc., 480 cc. and 3.84 liter bottles. Contains 0.1 per cent cetyl pyridinium chloride in a tincture medium of 50 per cent ethyl alcohol by volume and 10 per cent acetone by volume.

Solution Ceepryn 1:1,000 (Isotonic): 480 cc. and 3.84 liter bottles. Contains 0.1 per cent cetyl pyridinium chloride in distilled water made isotonic by addition of 0.26 Gm. of monobasic sodium phosphate and 1.43 Gm. of disodium phosphate per hundred cubic centimeters.

U. S. patent 2,295,504. U. S. trademark 398,185.

AMINOPHYLLINE--U.S.P. (See New and Nonofficial Remedies 1947, p. 305).

The following dosage forms have been accepted:

S. E. MASSENGILL COMPANY, BRISTOL, TENN.

Tablets Aminophylline: 0.1 Gm. and 0.19 Gm.

KREMERS-URBAN CO., MILWAUKEE.

Tablets Aminophylline. 0.1 Gm. and 0.2 Gm.

Solution Aminophylline with Benzyl Alcohol 2 per cent: 0.24 Gm. 10 cc. ampuls; 0.48 Gm. 2 cc. and 20 cc. ampuls.

PENICILLIN (See New and Nonofficial Remedies 1947, p. 144).

The following dosage forms have been accepted:

BRISTOL LABORATORIES, INC., NEW YORK.

Crystalline Penicillin G Sodium in Oil and Wax (*Free Flowing*): 300,000 units per cc. suspended in peanut oil containing 4.8 per cent (W/V) white wax U.S.P., 1 cc. cartridges and 10 cc. vials.

LEDERLE LABORATORIES DIVISION, PEARL RIVER, N. Y.

Crystalline Penicillin G Sodium (*Buffered*): 100,000, 200,000 and 500,000 unit vials with sodium citrate U.S.P. as a buffer.

COMMERCIAL SOLVENTS CORPORATION, NEW YORK.

Crystalline Penicillin G Potassium: 1,000,000 units, 50 cc. vials.

Crystaline Penicillin G Potassium in Oil and Wax (*Free Flowing*): 300,000 units per cc., 10 cc. vials.

E. R. SQUIBB & SONS, NEW YORK.

Troches Penicillin Calcium: 5000 units.

RIBOFLAVIN (See New and Nonofficial Remedies 1947, p. 511).

The following dosage form has been accepted:

THE WM. S. MERRELL CO., CINCINNATI.

Tablets Riboflavin: 5 mg.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies 1947, p. 347).

The following additional dosage form has been accepted:

E. S. MILLER LABORATORIES, INC., LOS ANGELES.

Solution Diethylstilbestrol in Oil with Benzocaine 2 per cent: 0.5 mg. per cc., in sesame oil with Benzocaine 2 per cent, 1 cc. ampuls. Preserved with cresol 0.5 per cent

EDITORIAL ANNOUNCEMENT

The absence of the compositors from their work continues. This issue of THE JOURNAL has been prepared in part by the use of *Vari-Typer* machines.

ROLE OF DIETARY PROTEIN IN FORMATION OF HEMOGLOBIN

Until recently the fact that an adequate dietary intake of protein is essential for normal formation of hemoglobin has been assumed without definite proof. The basis for such an assumption is, of course, the fact that hemoglobin is a protein and hence must be ultimately derived from the protein of the diet. This logical conclusion has been established with some difficulty, however, because of the interconvertibility of the various body proteins and because formation of hemoglobin has a "high priority" for any protein available for metabolism. Rather prolonged and drastic dietary restriction of protein is therefore necessary before formation of hemoglobin is decreased and a demonstrable anemia results. This fact has been clearly demonstrated by Whipple and his collaborators[1] in the dog and by several investigators in the rat.[2] As an extension of this thesis Wayne University investigators[3] have obtained evidence that not only the quantity but also the quality of dietary protein affects formation of hemoglobin. The feeding of a protein deficient in one of the essential amino acids, isoleucine, for example, resulted in the development of a mild chronic anemia, whereas the feeding of the same amount of a protein, lactalbumin, containing adequate quantities of all the eseential amino acids supported normal hemopoiesis. Furthermore, regeneration of hemoglobin after hemorrhage was much less active in animals fed the qualitatively deficient protein than in animals fed lactalbumin. Supporting evidence has been obtained by other investigators, who have shown that a dietary deficiency of certain other essential amino acids, including lysine and tryptophane, limits formation of hemoglobin in the rat. This convincing array of experimental evidence led to the conclusion[3] that "a combination of amino acids in as yet undertermined proportions is needed for the synthesis of the hemoglobin molecule "and to the emphasis on "both the quality and quantity of dietary protein for hemopoiesis."

The essential role of dietary protein in the synthesis of the porphyric portion of the hemoglobin molecule has lately been demonstrated. Isotopically labeled nitrogen of glycine, administered orally to human subjects, appears in the hemin prepared from the subject's red blood cells,[4] and the feeding of a diet low in protein to rats decreases formation of porphyrin as manifest by a decrease in the fecal excretion of protoporphyrin.[5]

Recent studies indicate that the experimental observations cited have practical clinical applications. Following blood loss in human subjects, regeneration of hemoglobin is more rapid if the diet contains generous amounts of protein.[6] Currently, Wintrobe and his co-workers[7] have suggested that the anemia of infection may result from the lack of protein for hemoglobin formation due to the negative nitrogen balance found in this condition.

INTRAVENOUS NUTRITION

The parental administration of nutrients has proved of vital importance in medicine. Dextrose, salt and water given intravenously have long been a dependable device for providing fluid, electrolyte and energy; to this mixture more recently proteins or protein derivatives such as casein digests or mixtures of amino acids have been added, thus amplifying the adequency of the nutrition. In peritoneal lavage, solutions resembling the electrolyte pattern of blood are injected into the body cavity. Preparations of its fat-soluble vitamins are available for intramuscular injection, though their utilization by this route is less complete than when given orally. Currently, one of the drawbacks of intravenous alimentation is the inability to supply the required calories; the addition of fat to the infusion mixture would tend to remedy this deficiency.

Studies have been reported recently indicating the satisfactory use of fat for intravenous alimentation in experimental animals. Refined coconut oil emulsions stabilized with purified phospholipids from soybeans[1] were prepared by using a high pressure homogenizer; all the lipid particles were less than 2 microns in diameter, and most of them were beyond the resolving power of the light microscope.[2] Furthermore, these preparations were unchanged during autoclaving. They were injected intravenously into dogs in amounts approaching the usual oral intake of fats. The 30 per cent emulsion supplied approximately 3 calories per cubic centimeter of preparation and was as well tolerated as was the 15 per cent emulsion used earlier.[3] The plasma fat showed a definite increase to approximately twice the normal value during the intravenous administration.[3] With the cessation of injection there was a prompt fall in the plasma fat to pretreatment level within one hour, indicating that the lipid rapidly left the circulation. The granulomatous lesions in the lungs observed in the early experiments were eliminated after further fractionation of the soybean lecithin stabilizer. Animals have been given the improved emulsion intravenously for as long as eighty-four days without untoward results.[4]

With the successful incorporation of fat into mixtures for intravenous administration. the possibilities for parenteral alimentation are greatly enhanced. Not only can the three major organic food materials be provided along with salts, vitamins and water, but the high caloric value of fats permits the approach to the body's needs for energy. Once the foregoing procedures have been satisfactorily adapted to clinical needs, an additional important contribution of nutrition to medicine will have been recorded.

Current Comment

ONE STAGE RESECTION AND ANASTOMOSIS OF THE COLON

The pendulum of surgery of the large intestine, according to Hinton,[1] has returned to primary resection with primary anastomosis, with or without a complementary ileostomy or colostomy. The early experiences with this method were discouraging. Billroth, in an analysis of 17 patients operated on by the one stage method, reported a mortality of 60 per cent. The exterioization method first practiced by Heinecke, by Paul, and by Bloch, and made popular by von Mikulicz, reduced the mortality from 60 per cent in the material of Billroth to 16.6 per cent in the cases reported by von Mikulicz. The multiple stage exteriorization operation or one of its modifications is now considered the operation of choice for resection of the colon at all levels, excluding the rectum. Despite its many advantages, especially in cases of obstruction of the bowel, the method presented certain definite disadvantages. Multiple operations, according to Hinton, mean multiple risks. Other objections are high incidence of complications, such as wound disruption, wound infection, persistent fistulas and postoperative hernias. Convalescence and hospitalization are prolonged; the artificial anus is an annoyance. The sole argument of low mortality rate following the multiple stage operation has been recently challenged by the reports of a number of surgeons who have been performing the one stage resection with a primary anastomosis with or without a primary colostomy or ileostomy. Thus Gibbon and Hodge[2] reported a mortality of only 14 per cent in their own material and in that of MacFee, Wilkie and Stone and McLanahan, representing a total of 246 patients operated on by the primary aseptic colonic resection. The one stage resection is advocated only for the patient who is not suffering from obstruction of the bowel. Babcock and Bacon,[3] as well as others, considered that in such a patient a primary proximal colostomy or ileostomy is not necessary. Hinton and Localio report 26 consecutive colonic resections involving the various regions of the colon above the peritoneal reflection performed in one stage without a proximal colostomy or ileostomy with a mortality of 3.8 per cent. The striking improvement with the one stage method was made possible not so much by the refinement of the technic of bowel anastomosis as by the recent advances in the preoperative and postoperative care of the patient. Among these should be mentioned correction of the fluid and electrolyte balance, transfusion of whole blood for anemia, correction of hypoproteinemia and of vitamin deficiencies. The preoperative and postoperative administration of succinyl sulfathiazole tends to render the bowel more or less aseptic. The use of the Miller-Abbott tube or the Levine tube aids in keeping the bowel deflated. The consensus seems to be that one stage resection is a safe procedure. Recent reports by Waugh[4] give a mortality rate of 4 per cent in 50 consecutive patients after primary resection of lesions of the left half of the colon; Dixon[5] reports a mortality rate of 2.4 per cent in 41 patients, and Wangensteen[6] a mortality rate of 1.6 per cent for 60 resections for lesions of the colon and the rectosigmoid.

REAGINS IN NASAL SECRETIONS

Nasal secretion has been suspected by numerous clinicians as an important factor in the mechanism of respiratory allergies. Samter and Becker[1] of the Allergy Unit, University of Illinois, tested the reagin content of nasal secretions in 10 ragweed-sensitized patients, two months after the ragweed season, using as controls nasal secretions from nonallergic persons. Nasal secretions were obtained by inserting a cotton plug saturated with 10 per cent sodium chloride solution into each nostril. Satisfactory response was usually obtained within ten minutes. The secretions thus obtained were passed through a micro-Seitz filter. The resulting cell-free liquid was used for passive transfer tests; 0.1 cc. of the liquid was injected into each of four sites in the left arm of normal persons whose skin tests had previously been negative to ragweed extract. Twenty-four hours later reinjections were given at these sites with 0.02 cc. of ragweed extract. Control tests for sensitivity to ragweed were made on unprepared skin of the same persons. The test showed that the nasal secretions of 7 of the 10 sensitized patients contained demonstrable amounts of ragweed reagin. All nasal secretions from normal persons were negative. Control tests with alder extract were also negative. The reagins thus demonstrated were therefore apparently specific for ragweed. These observations lead to a better understanding of the mechanism of respiratory allergy.

WORLD HEALTH ORGANIZATION

The Congress of the United States has passed and the President has signed a joint resolution which provides for membership and participation by the United States in the World Health Organization. Under the resolution as finally passed, the President designates from time to time to attend any specified session or session of the World Health Organization not to exceed three delegates of the United States and such alternates as may be consistent with the rules of procedure. One of the delegates is designated as the chief delegate. When the United States becomes entitled to designate a person to serve on the Executive Board of the World Health Organization, the President is authorized to designate a representative of the United States by and with the advice and consent of the Senate, and may designate one alternate This representative must be a graduate of a recognized medical school and must have spent not less than three years in active practice as a physician or surgeon. The representative is entitled to be paid at a rate of $12,000 per year and his alternate at $10,000 per year for such periods as the President may specify. The resolution also provides that the contribution of the United States should not exceed $1,920,000 per year and a sum not to exceed $83,000 per year for paying expenses incident to the United States' participation. The resolution also provides that nothing in the constitution of the World Health Organization in any manner commits the United States to enact any special legislative program regarding any matters referred to in the constitution. The American Medical Association has supported participation by the United States in the World Health Organization. The possibilities for the advancement of medical science, for better control of epidemics than has previously been possible, for standardization in many fields of medical service are exceedingly great. Among the three representatives appointed by the United States to attend the first assembly of the World Health Organization is Dr. James R. Miller of Hartford, Conn., a member of the Board of Trustees of the American Medical Association. The other members in attendance at the first assembly will be Drs. Thomas Parran and Martha Eliot. The United States does not attend the first session as a member because of the lateness of action in joining, so that these representatives appear at the first session as observers.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

June 18, 1948.

Draft Bill Makes Doctors Subject to Special Calls

Final action is expected by the House this week on the draft bill. As passed by the Senate by an overwhelming 78 to 10 vote, the bill would require doctors and dentists, aged 18 through 44, to register and be subject to special calls. Medical men educated at government expense or those who were deferred during the war would be called first. The bill is aimed at bringing up the nation's peacetime forces to a record of 1,936,000 men. It would make most nonveterans, 19 through 25, subject to two years in the ranks. Men with dependents would be deferred. House leaders promised to bring the bill to a vote before the proposed June 19 adjournment.

Development of a Low Cost, Easily Operated Geiger Counter Sought

The Civil Defense Planning unit of the National Defense Department revealed that an urgent need for medical defense against atomic bomb attacks is development of low cost, easily operated geiger counters. They now range from $210 to $1,000 each. They are a prime civilian need to enable civilians to spot lingering, atomic death rays. Only a few of those now in use are considered suitable for detecting the area of a bombed city which had been made unsafe by radioactivity. The Army is now buying a small number of detectors for research and development work. The Civil Defense unit proposes the creation in each state of mobile units, trained and outfitted with instruments to detect radioactive poison left by an atomic bomb or some future atomic development. Officials declare that logical sources of personnel for such units would be doctors, chemistry and physics teachers, x-ray technicians and similar specialists. Training programs have been started through medical organizations, colleges and similar groups.

Capt. Melville J. Aston Heads Naval Medical School

The Navy Department announced that Captain Melville J. Aston has been ordered to command the Naval Medical Center in Bethesda, Md. He has been senior medical officer at the Norfolk Naval Shipyard, Portsmouth, Va.

Congress Approves Increases in Social Security Benefits

Both Houses of Congress approved multi-million dollar increases in Social Security payments to dependent children, the aged and the blind. The bill went to the White House for signature. It adds $184,000,000 annually to benefits received by 3,500,000 needy persons. Legislation increases the federal Social Security contribution to the states by $5 a month for the aged and blind and $3 a month for dependent children. Maximum is $50 for each aged and blind person and $27 for a dependent child. The increase was tacked onto a bill blocking extension of Social Security insurance to some 750,000 persons, chiefly salesman over whom employers do not exercise direct control.

Medical Legislation

STATE LEGISLATION

Kentucky

Bill Enacted.—S. 197 was approved March 29. It provides for the creation and establishment of a division of medical hospitals and related services in the department of health to make a survey of hospital facilities throughout the state and to accept federal funds to assist in the construction of additional needed facilities. The law requires the appointment of an advisory council and the preparation of necessary regulations and standards pertaining to the conduct and operation of hospitals constructed by virtue of the act.

Louisiana

Bills Enacted.—H.Res.6 was adopted May 21. It directs the Committee on Charitable Institutions to visit any and all of the charitable and eleemosynary institutions of the state and to make any necessary recommendations which it deems appropriate. S.Con.Res.4 was adopted May 20. It directs the Department of Institutions to take appropriate action to provide better hospital facilities for the indigent sick and to consider the installation of adequate free ambulance service and the establishment in private hospitals of charity beds on a contractual basis.

Massachusetts

Bill Introduced.—H.2318 proposes that insurers and self-insurers under the workmen's compensation law shall be charged for laboratory and roentgenologic service fees as a part of the reasonable cost of a physician's services.

Bills Enacted.—H.69 has become chapter 270 of the Laws of 1948. It provides that no corporation shall conduct a dental office and no person shall conduct a dental office under any name other than that of the dentist actually owning the practice. S.349 has become chapter 359 of the Laws of 1948. It authorizes medical service corporations to contract with hospital service corporations for the joint or cooperative administration of their affairs.

Missouri

Bill Enacted.—H.482 was approved May 10. It authorizes counties to levy a tax for the purpose of operating or maintaining public county health centers or institutions therein.

New Jersey

Bill Introduced.—A.Con.Res.13 proposes the creation of a committee to investigate and study the subject of licensing and regulating the practice of chiropractic.

Bills Enacted.—A. 101 has become chapter 42 of the Laws of 1948. It authorizes the commitment in the county hospital, or other hospital, of any person who fails to obey the rules or regulations promulgated by the state department of health for the care, prevention or spread of tuberculosis, if such person is an actual menace to the community or the children in his household. A. 137 has become chapter 53 of the Laws of 1948. It authorizes municipalities which have no municipal hospital to make appropriations each year to be applied to the purpose of paying the cost of supporting and maintaining indigent patients in hospitals in the municipality supported by private charity.

Rhode Island

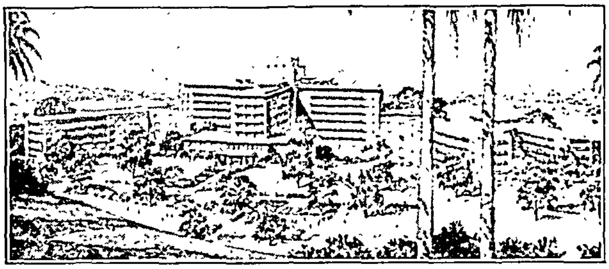
Bill Enacted.—H.698 was approved April 30. It authorizes every superintendent of schools to cause such further examinations to be made of school children as he shall deem necessary for the purpose of guarding against any further outbreaks of infantile paralysis within the schools of any city or town. Such examinations shall include examinations of the legs and pedal extremities of such children by physicians, school nurses or persons qualified to make such examinations.

GOVERNMENT SERVICES

ARMY

THE NEW TRIPLER HOSPITAL

One of the most extensive construction projects ever undertaken in Hawaii is the new 1,500 bed U. S. Army Tripler General Hospital located at Moanalua, Oahu. Situated on the slopes of the Koolau Mountain Range, the hospital will occupy about 365 acres with a magnificent view of the island's southern coastline and thus take full advantage of the prevailing cool mauka winds. The design of the new hospital, the finest in the Army's system, will keep it abreast of the times for years to come. The neuropsychiatric section will be an individual unit where separate recreational, occupational therapy, physical therapy and eating facilities can be provided without the atmosphere common to hospitals caring for patients of this type. Physical reconditioning and recreational facilities have been incorporated here for the first time in a permanent hospital. The pathology department includes an amphitheater seating seventy-five persons for lectures and demonstrations. Since Hawaii lies within the earthquake zone, structural frames have been designed to resist lateral forces greater than those produced by the severest earthquake of record. The main structure is divided into twelve individual units, each structurally isolated from adjacent units. A distinctive feature is the use of aquamedia, or canopies, which afford protection from sun or rain and create a pleasant streamlined impression. With thirteen elevators located at strategic points, the primary flow of all hospital traffic is vertical rather than horizontal, permitting members of the staff and patients to pass quickly from one ward to another. The operating suite contains seven operating rooms, immediately above which is a complete recovery ward where patients can be given the closest attention immediately following surgical intervention. In this section outlets for oxygen piped from a central storage point are available for every bed. Suction outlets are also available for immediate emergency. All patients have access to the sheltered lanai where they may view the magnificent sunsets. At the end of each ward is a large day room which in normal times serves for recreation but which can be used for immediate expansion of the hospital in case of emergency. The Pearl Harbor disaster brought to the attention of this community the critical need for adequate Army facilities which the old Tripler Hospital could not satisfy. In 1942 it was necessary for the commanding general to commandeer three of Honolulu's schools to provide temporary hospital facilities. To relieve this condition Congress in June 1944 authorized construction of the new Tripler Hospital. A pneumatic tube system connects all wards and departments through a central clearing station, by means of which patient histories, laboratory and other reports can be sent instantaneously to any part of the hospital. The main building is fourteen stories high, the tallest building in Hawaii. In addition there are nurses' quarters, officers' quarters, enlisted men's barracks, an orthopedic brace shop and other buildings for special facilities and community service.



The new Tripler General Hospital at Moanalua, Oahu.

REACTIVATE DRUG RESOURCES ADVISORY COMMITTEE

The surgeons general of the Army and Navy and Mr. C. P. Frailey, secretary, American Drug Manufacturers Association, announce that the World War II Drug Resources Advisory Committee has been reactivated. The new committee of fourteen members will hold its first meeting in June, when the status of domestic productive capacity and raw material stocks will be reviewed. Members of the committee serve without compensation and bear all operating expenses. The committee will be maintained as an industrywide function with no connection with any trade organization; it will immediately resume its wartime advisory functions in anticipation of civilian needs as well as those of military service.

ARMY MEDICAL LIBRARY

The Army Medical Library has furnished more than 1,000 volumes of medical literature to libraries in seven different nations to replenish their war-depleted stocks. This was in addition to literature previously furnished by the library to Belgium, China, France, Great Britain, Hungary and Yugoslavia.

In April the library sent twenty-one volumes of the Index-Catalogue to the Institute Superiore de Sanita in Rome to complete their set and deposited series III and IV in Veterinarhogskolans Bibliotek in Stockholm.

AN AUDIOLOGY MEETING

The Army sponsored a meeting in Washington, D.C., June 5, of persons interested in rehabilitation of Army and Navy personnel, Veterans Administration beneficiaries and civilians with impaired hearing. The purpose of the meeting was to evaluate the work being done and to plan a better organized program in the services and in civilian groups. The afternoon was given over to a tour through the Aural Rehabilitation Center at Forest Glen, Md. Among the speakers were Fred W. Kranz of Elmsford, N. Y.; Norton Canfield of Yale University School of Medicine, who reported on the meeting of the committee on hearing of the National Research Council; Merle Ansberry of Veterans Administration; Warren H. Gardner of the Cleveland Hearing and Speech Center, and D. W. Morris of Ohio State University; William G. Hardy of Johns Hopkins Hospital was moderator of a discussion on speech, lip reading, acoustics and auditory training.

NAVY

NEW MEDICAL TRAINING PROGRAM

The Surgeon General of the Navy has announced the expansion of the Bureau's professional training program for reserve and regular medical officers, which is similar to the recently expanded Army medical training program. The object is to permit more Navy doctors to meet the requirements for certification by the various American specialty boards and to encourage the young doctor to intern under the auspices of the Navy. The following are the important points in this program.

Graduates of class A medical schools who have been accepted for internship by a hospital approved for such training by the Council on Medical Education and Hospitals of the American Medical Association may be commissioned as lieutenants (junior grade), MC, USNR, and permitted to continue their intern training. They will receive all the pay and allowance of the rank while so serving. After completing their internships, the medical officers must remain on active duty for a period of one year. If they meet the professional, physical and moral requirements, they will be given every encouragement to transfer to the regular Navy.

Interns who have completed the one year of obligated service and who have transferred to the regular Navy may be considered for residency training on a competitive basis with other officer personnel of the regular Medical Corps.

Resident physicians now in civilian hospitals, or those accepted for approved residency training, are eligible for commissions in the regular Navy. Those so commissioned will be assigned to duty, with full pay and allowances, in the hospital in which they are already a resident or to which they have been accepted for residency training. Every attempt will be made to permit residents holding commissions in the regular Navy to complete their training in event of an emergency.

The Navy has at present 400 approved residencies and fellowships in the various specialties recognized by the American Specialty Boards in Naval and civilian hospitals. This educational training involving the 400 residencies is divided into two programs.

Program A: One hundred of these residencies, courses and fellowships will be made available for civilian physicians accepting a commission in the Navy. An additional hundred civilian physicians will be commissioned in the Navy and permitted to pursue their own course, fellowship or residency, provided that it is approved by the Council on Medical Education and Hospitals of the American Medical Association with concurrence of the Specialty Board. On acceptance of the designated training, they will be required to agree to remain in the Navy for a certain obligated time.

If on original appointment a candidate has not been approved for more than one year of training, during his first year of residency training (program A) he may compete for 1 of the 300 residencies (program B) available to the Regular Naval medical officers, and if he obtains such training he will obligate himself to remain on active duty for an additional period depending on the amount of time spent in training.

Program B: Three hundred residencies, fellowships or courses will be reserved for continuing the training program as presently organized for regular medical officers.

The obligated service following graduate medical training (courses, fellowships and residencies) in Naval hospitals is one year for each year of training received.

Information concerning any part of the program may be obtained by writing the Chief of the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C.

NAVAL CAREER IN RESEARCH

The Bureau of Medicine and Surgery has added the field of research to the list of specialties for which medical officers may qualify and thus be assured of spending a major part of their Naval career in research. While the qualifications required for this specialty are not inflexible, it is desirable to have a Ph.D. in one of the basic medical sciences. However, the application of any officer of the Naval Medical Department having an interest in research as a career will be considered, and if such training is indicated he will be started on a tour of duty at one of the Naval Medical Research Institutions, followed later by short tour of sea duty to provide an over-all picture of the Navy's needs. Training in civilian research laboratories will be offered also. Applications are desired from physicians and other scientists now in the Naval Reserve and also from qualified civilians interested in a career of naval medical research.

PERSONALS

Dr. Henry L. Bockus, professor of gastroenterology at the University of Pennsylvania Graduate School of Medicine, Philadelphia, spoke on "The Present Status of Management of Peptic Ulcer Disease" at the Navy Medical Center, Bethesda, Md., May 14. This was the last of the present series of guest lectures.

Lieut. Comdr. Vernon T. Palmer, after more than thirty years in the Hospital Corps of the Navy, retired May 3 and will make his home in Seattle. Formerly a chief pharmacist in the Navy, he was awarded the Bronze Star for meritorious service with the 3d Amphibious Corps during the landings on Bougainville, Guam, Palau and Okinawa.

Comdr. Fred G. Hirsch (MC) addressed the New York Academy of Medicine April 29 on "Relationship Between the Electro-Conductivity and Erythrocyte Concentration in the Blood."

AWARDS AND COMMENDATIONS

Dr. Sumner L. Koch

The Certificate of Merit has been awarded to Dr. Sumner L. Koch, associate professor of surgery, Northwestern University Medical School, Chicago, for his outstanding contribution to the war effort while a member of the Subcommittee on Infected Wounds and Burns of the National Research Council. The new compression technic used in place of tannic acid and gentian violet in the treatment of burns was a product of the research and experiments which he directed.

Dr. Winfred Overholser

The Bureau of Medicine and Surgery on April 22 presented a Certificate of Appreciation to Dr. Winfred Overholser, superintendent of St. Elizabeths Hospital, Washington, D. C., and a Certificate of Achievement to that hospital. The certificates were awarded in recognition of the valuable assistance rendered by St. Elizabeths Hospital and by Dr. Overholser, personally, to the Medical Department of the Navy during World War II in the training of Navy medical personnel and treatment of Navy patients.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Research Society Formed.—The Medical Research Society of Southern California was recently formed to further high standards of medical research and education and to foster public interest in the need of research. Dr. Charles M. Carpenter, professor of infectious diseases, Medical School of the University of California, Los Angeles, has been elected chairman. Advisory council members are deans of Southern California medical schools: Dr. Walter E. Macpherson, College of Medical Evangelists; Dr. Burrell O. Raulston, University of Southern California School of Medicine; Dr. Stafford L. Warren, Medical School of the University of California, Los Angeles campus, and Dr. Lewis T. Bullock of the Los Angeles County Medical Society.

CONNECTICUT

Faculty Appointments and Promotions.—Yale University School of Medicine, New Haven, announces the following appointments and promotions. Dr. Thomas R. Forbes, assistant professor of anatomy, becomes assistant dean of the School of Medicine in charge of student affairs, succeeding Donald H. Barron, Ph.D., associate professor of physiology. Those promoted to associate professorships include Drs. John R. Brobeck, physiology; Clement C. Clay, hospital administration, and Fredrick C. Redlich, department of psychiatry and mental hygiene. Assistant professors include: Drs. Helen R. Gilmore, who will be in charge of the psychiatric inpatient clinic; William W. Engstrom and Henry D. Hoberman, medicine; Arnold H. Janzen, radiology, and Dorothy M. Horstmann, preventive medicine. Dr. Leonell C. Strong, research associate in anatomy, was promoted to the rank of professor. Clinical appointments include: Drs. Aloys G. Ansprenger, assistant clinical professor of radiology; James M. Cunningham, lecturer in psychiatry and mental hygiene, promoted to the rank of associate clinical professor; Gideon K de Forest, assistant clinical professor of medicine; Russell V. Fuldner, lecturer in anatomy and assistant clinical professor of orthopedic surgery; Mildred H. January, assistant clinical professor of pediatrics and psychiatry and mental hygiene, and Bernard L. Kartin, assistant clinical professor of medicine.

GEORGIA

Personal.—Dr. Robert Rogers, Gainesville, has been elected chairman of the State Board of Health to succeed Dr. Charles L. Ridley, Macon.

State Medical Election.—At the annual meeting of the Medical Association of Georgia, April 27-30, Dr. Edgar H. Greene, Atlanta, became president and Dr. Enoch Calloway, LaGrange, became president-elect. Dr. Edgar D. Shanks, Atlanta, was reelected secretary treasurer.

Typhus Menace Reduced.—The state department of public health carried on ddt dusting and rat eradication activities in seventy-six Georgia counties in 1947, with the result that in five of the most densely populated counties, comprising one fourth of the state's population, the number of typhus cases decreased 57 per cent over 1946 and 92 per cent over 1945, when DDT dusting was begun. From a total of 1,111 cases of typhus reported in 1945, the number dropped to 436 in 1947, a decline of 61 per cent for the state as a whole. DDT dusting was extended in 1947 to include farm residences and outbuildings and more than 182,787 premises were dusted, nearly 35,000 more than in 1946. Poison bait was also used in some areas, and ratproofing buildings, refused collecting and sanitary land fills were also employed.

ILLINOIS

Fewer Cases of Communicable Disease.—The state department of public health reports that the number of cases of most communicable diseases in the first thirteen weeks of 1948 were fewer than those reported in 1947. Outstanding exceptions were measles and mumps, of which Illinois experienced "minor epidemic waves." Twenty-eight cases of diphtheria were reported in the first quarter of 1948, a decrease of 16 cases for the corresponding period in 1947. This is the lowest ever recorded in Illinois. Poliomyelitis morbidity reports show a decrease of 68 per cent from those for 1947.

Chicago

Research in Blood Diseases.—The Hematology Research Foundation recently celebrated the achievement of its goal of $25,000 to advance the study of leukemia and other blood diseases. The money raised by the foundation is given to Michael Reese Hospital to support this research.

Film to Record Cancer Growth.—Northwestern University Medical School, by means of automatically focused motion picture camera, will start this fall to record over an extended period growing cancer cells. John Nash Ott Jr., Winnetka, has been commissioned to do the photographic work in an air-conditioned, underground laboratory, under the direction of Dr. William B. Wartmen, Morrison professor and chairman of the department of pathology.

Rotary Club Devotes Session to Tuberculosis.—The Rotary Club of Chicago, at its meeting in the Sherman Hotel, June 1, considered "Tuberculosis: Its Problem and Solution." The speakers were Drs. Morris Fishbein, Editor of THE JOURNAL; Herman N. Bundesen, president, Chicago Board of Health, and James H. Hutton, chairman, committee on tuberculosis control, Chicago Medical Society, who acted as chairman.

Hektoen Institute Awards.—Hektoen Institute for Medical Research of the Cook County Hospital won the following prizes at the Illinois State Medical Society Scientific Exhibits: Gold Medal, educational value, "Amino Acids in Clinical Medicine," Drs. Karl A. Meyer, Donald D. Kozoll, William S. Hoffman, Frederick Steigmann and Hans Popper; Bronze Medal, original investigative work, "Radioactive Isotopes in Peripheral Vascular Work," Drs. Morris T. Friedell, Fenton Schaffner, William J. Pickett and Irvin F. Hummon.

Instructorship Awards.—Drs. Henry G. Poncher and Eric Oldberg were named by the senior students at the University of Illinois College of Medicine as winners of the Raymond B. Allen Instructorship Award, designed to honor excellency in individual instructorship rendered by faculty members to students. Dr. Poncher, head of the department of pediatrics, was honored for clinical instruction. The award for excellency in didactic instruction has been given to Dr. Oldberg, head of the department of neurology and neurological surgery. Recipients of instructorship awards from other classes are as follows: junior class—Dr. Poncher for clinical instruction and Dr. Isadore A. Rabens, clinical associate professor of medicine, for Pfeiffer, head of the department of pharmacology and pharmacognosy; freshmen class—tie between William J. Furuta, Ph.D., and Parke H. Simer, Ph.D., of the department of anatomy.

INDIANA

Health Association.—Dr. Walter L. Portteus, Franklin, became president of the Indiana Public Health Association at the annual meeting in Indianapolis. The principal speaker at the banquet was Dr. Cleon A. Nafe, Indianapolis, president of the Indiana State Medical Association.

General Practitioner Award.—The Indiana State Medical Association will present a medal to some outstanding general practitioner at the annual meeting in October. Each county medical society will be invited to submit a nomination to the council. The "Hoosier Doctor of the Year" will be the Indiana State Medical Association nomination for the American Medical Association's General Practitioner Award.

LOUISIANA

Personal.—Ernest Carroll Faust, Ph.D., professor of parasitology and head of the department of tropical diseases at Tulane University of Louisiana School of Medicine, New Orleans, has been elected honorary member of the Tropical Medicine Society of Belgium.

State Medical Election.—At the annual meeting of the Louisiana State Medical Society in Monroe, April 12-14, Dr. Edwin H. Lawson, New Orleans, was chosen president-elect, and Dr. Marion D. Hargrove, Shreveport, was installed as president. Dr. Valentine H. Fuchs, New Orleans, was named delegate to the American Medical Association 1949 and 1950, with Dr. George H. Hauser, New Orleans, named alternate. The next annual meeting will be held in New Orleans.

MASSACHUSETTS

Seminar on Health Education.—The Harvard Summer School and the Massachusetts Department of Public Health, Boston, will jointly sponsor a four week graduate seminar in health education. Opening on June 28, it will offer training in health education for school administrators, for teachers of nutrition, social studies, health and physical education and for members of agencies in the school health field.

Massachusetts General Appoints Research Committee.—A scientific advisory committee has been appointed at Massachusetts General Hospital, Boston, to review research projects, advise on policies and inform the hospital trustees on the general value of present and future research. Dr. Walter Bauer, Boston, is chairman of the committee. Members of the committee from Harvard Medical School are Drs. C. Sidney Burwell, dean; John Homans, Eugene M. Landis and J. Howard Means; others are Karl T. Compton, president, Massachusetts Institute of Technology, Cambridge; Carl F. Cori, St. Louis, co-winner of the Nobel Prize in Medicine, 1947; Nathaniel W. Faxon, director of the hospital; Edward D. Churchill, and Herbert S. Gasser, director, Rockefeller Institute. The hospital feels that the presence of distinguished scientists from other parts of the country gives the committee a broader perspective on research problems than would otherwise be possible.

MICHIGAN

Honor Veteran Doctors.—Citizens of Marine City on April 4 honored two of their physicians, Drs. Thomas E. DeGurse and Aaron B. Armsbury, at a testimonial dinner. Dr. DeGurse was recently chosen "Michigan's Foremost Family Physician" by the state medical association. Dr. Armsbury completed fifty years of practice in Marine City March 17. Both men have also served the community in civic positions.

Women Physicians Establish Scholarship.—The Dr. Esther H. Dale Scholarship Fund has been established by Nu Sigma Phi, a women's medical sorority at the Wayne University College of Medicine, Detroit, in honor of Dr. Dale's achievements in medicine and in sorority activities. The scholarship will aid promising women medical students who need help with their education. Dr. Dale, a 1941 alumna of the college of medicine, is an instructor in pathology there. She is also National Noble Grand of Nu Sigma Phi and past president of the Blackwell (Michigan) branch of the American Women's Medical Association.

MINNESOTA

Fake Eye Specialist Imprisoned--Elliot Wilkinson, 54, Dallas, Texas, was sentenced to not more than five years at hard labor in the Minnesota Prison at Stillwater, by the judge of the Finkelnburg District Court, Winona. Wilkinson pleaded guilty to an information charging him with grand larceny in the second degree. He was arrested on May 9 by Winona police after he had swindled a Winona County farm woman out of $60 by falsely representing himself as an eye specialist from Chicago, and further stating that the patient had cataracts. Wilkinson's record (THE JOURNAL Dec. 10, 1927, page 2047; July 2, 1932, page 41; Jan. 2, 1937, page 55) includes a sentence of five years in 1932 in the State Prison at Stillwater for grand larceny in the first degree, growing out of a $1,500 swindle perpetrated in 1924; seven years in the Federal Prison at Atlanta, Ga., for using the mails to defraud, and 5 years in the Virginia State Prison at Richmond. To farm people Wilkinson represented himself as an eye specialist; after diagnosing the case as cataracts, he would extract a large sum of money from the patient. He would insert a liquid preparation into the eye and then show the patient a small piece of tissue paper which he represented as being the cataract.

NEW JERSEY

Society News.—A Physicians' Art Association of New Jersey, open to all members of the Medical Society of New Jersey, has been organized, with Dr. Robert A. Giuliana, Newark, president, and Dr. Marvin C. Becker, Newark, secretary.

Community Honors Physician.—The entire rural Hunterdon County community met in the school gymnasium at Bloomsbury, April 17, to honor Dr. Edgar W. Lane on his completion of thirty years of service. Dr. Lane is a graduate of the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1915.

NEW YORK

Personal.—Dr. Stanley W. Sayer, Gouverneur, district state health officer in charge of the Gouverneur District, retired April 7 after more than thirty years' service on the staff of the New York State Department of Health.

Institute on Community Nutrition.—A second Community Nutrition Institute, sponsored by Syracuse University and the New York State Department of Health, will be presented July 5-17 at Washington Arms, Syracuse. July 5-10 the discussion of technics in community nutrition will include the place of nutrition in the public health program, food planning, how to get the public to use nutrition information, psychologic factors affecting nutrition and relationships of professional personnel with the client. The second week will include a discussion of nutrition in maternal and child health, the role of nutrition in postponable diseases, its relation to susceptability to disease, and nutrition in work performances.

New York City

Columbia Appointments.—The following appointments to the staff of the Columbia University College of Physicians and Surgeons were announced recently and will be effective July 1: Dr. Samuel M. Peck, associate clinical professor of dermatology; Drs. Louis E. Siltzbach, Solomon Silver and Louis J. Soffer, assistant clinical professors of medicine, and Dr. Arthur S. W. Touroff, clinical professor of surgery.

Positions Available in Neuropathology.—Kings County Hospital, Brooklyn, has available a full time and a half time position in neuropathology The new neuropathologic laboratory is a part of the new psychiatric facility. This is a teaching hospital, and the work would comprise service to the psychiatric, the neurologic and the neurosurgical departments of the hospital. Applicants should address inquiries to Dr. Sam Parker, Director of Psychiatry, Kings County Hospital, 606 Winthrop Street, Brooklyn 3, stating their background and qualifications.

Winners of Scholarships in Ophthalmology.—New York University College of Medicine has announced that Drs. Goodwin M. Breinin and Walter J. Maher, New York, Drs. Edwin H. Kent, Riverside, Conn., and Charles H. Toomey, Lakewood, Ohio, won the third annual New York City Lions' Club Scholarships for graduate training in ophthalmology. They will study special phases of eye conservation at Bellevue Hospital under the direction of Dr. Daniel B. Kirby, chairman, department of ophthalmology, New York University College of Medicine. The awards were made at a Lions club luncheon on June

Incoming Patients to Be X-rayed.—Morrisania City Hospital in the Bronx inaugurated in May the procedure of routine roentgen examinations of all incoming patients to discover whether they have tuberculosis. Detection of tuberculosis before admission will permit the hospital to safeguard its staff and patients and will make it possible to treat the patients immediately. The procedure is a joint project of the Bronx Committee of the New York Tuberculosis and Health Association and Morrisania Hospital. The association is providing the x-ray machine and technicians to operate it, and the hospital will be responsible for clinical study and follow-up on patients discovered to have tuberculosis.

PENNSYLVANIA

Cancer Detection Program.—A cancer detection program has been established in Fayette County. Sixty doctors of the county will act as examiners of well patients to insure early diagnosis. Patients may make appointments at information centers and be examined by a doctor chosen from a list there. The examination fee is $5, but in the case of indigents the American Cancer Society assumes this obligation. The program has received the full endorsement of the Fayette County Medical Society.

Philadelphia

Foundation Aids Research in Dermatology. An outright grant of $100,000 has been made to the University of Pennsylvania by the Rockefeller Foundation for the continuing development of the research program of the department of dermatology in the School of Medicine. The grant will be used to investigate fundamental problems related to disturbances of the skin. According to Dr. Donald M. Pillsbury, professor of dermatology and syphilology and chairman of the department in the Graduate School of Medicine at the University, the grant will make it possible to take full advantage of the facilities for research in the Hospital of the University of Pennsylvania, the Skin and Cancer Hospital, Graduate Hospital of the University of Pennsylvania and Children's Hospital. Facilities for investigative work in the department of dermatology at the university are most complete.

WEST VIRGINIA

Special Society News.—During the recent annual meeting of the state medical association, the West Virginia Society of Anesthesiologists was organized with Dr. Delmas E. Greeneltch, Wheeling, president, and Dr. Arkie B. Bowyer, Charleston, secretary-treasurer. Other special societies meeting in conjunction with the state association elected officers as follows: West Virginia Heart Association, Dr. William A. Thornhill Jr., Charleston, president, and Dr. Fred S. Richmond, Beckley, secretary-treasurer. West Virginia Obstetrical and Gynecological Society, Dr. Wilbur E. Hoffman, Charleston, president, and Dr. Harry G. Steele, Bluefield, secretary-treasurer. West Virginia Association of Pathologists, Dr. William T. McClure, Wheeling, president, Dr. Walter G. J. Putschar, Charleston, president-elect and Dr. Milford L. Hobbs, Morgantown, secretary-treasurer. Dr. L. Rush Lambert, Fairmont, was elected president of the West Virginia Chapter of the Medical College of Virginia Alumni.

GENERAL

Booklet on Cerebral Palsy.—The National Society for crippled Children and Adults, Inc., is distributing a fifty-seven page booklet on "The Problem of Cerebral Palsy Today". Copies may be obtained from the society at 11 South La Salle Street, Chicago 3, at 25 cents each.

Society Election.—At the Atlantic City meeting of the Federation of American Societies for Experimental Biology, March 14-19, the American Institute for Nutrition elected Elmer M. Nelson, Ph. D. Washington, D. C., president and Joseph H. Roe, Ph. D., Washington. D. C., secretary

Appointed to Federal Security Administration.—J. Donald Kingsley has been appointed assistant federal security administrator to succeed Maurice Collins, Washington, D. C., who retired last September after thirty-five years of federal service. Mr. Kingsley served most recently as economic adviser to the International Labor Office in Geneva, Switzerland, and as chief of the I. L. O. mission to Greece.

Cancer Fellowships Available.—Clinical fellowships in the diagnosis and treatment of cancer have been established by the American Cancer Society, Inc., for young physicians of promise and may be secured through hospitals designated by the society that offer postgraduate training in malignant diseases, surgery, obstetrics and gynecology, orthopedic surgery, otolaryngology, urology, radiology, pathology and internal medicine. The one year fellowships, renewable to a total of not more than three years, carry a stipend of $2,400 to $3,600 per year.

Placement of Electron Microscopists.—The Electron Microscope Society of America has set up a placement service for the mutual benefit of its members and potential employers. The society has on its membership roll the names of every active electron microscopist in this country. Employers seeking scientists or technicians for work in this field may use the placement service. Inquiries should be directed to Dr. C. J. Burton, Secretary, Electron Microscope Society of America, American Cyanamid Company, Stamford, Conn.

Red Cross Blood Bank Project.—Dr. Ivan W. Brown, Duke University School of Medicine, Durham, N. C., has been appointed temporary assistant national medical and technical director of the national blood bank program of the American Red Cross. From headquarters in Washington, D. C., Dr. Brown will fly to any section of the nation to advise and assist in work on local blood bank projects. National administrator for the work is Rear Admiral Ross T. McIntyre. Dr. Brown is a graduate of Duke University School of Medicine 1939.

Medical Mission to Germany.—The Unitarian Service Committee has organized a medical mission to Germany. Fourteen lecturers will discuss anatomy, physiology, biological chemistry, pharmacology, internal medicine, surgery, gynecology and obstetrics, ophthalmology, psychiatry, pediatrics and otorhinolaryngology. The mission will be made up of Drs. Otto Krayer, Boston, chairman; Dallas B. Phemister, Chicago. vice chairman; and David G. Cogan, Boston; Lyman G. Craig, Ph. D., New York; Herman DeWilde, Boston; John T. Edsall, Boston; Francis D. W. Lukens, Philadelphia; Benjamin H. Robbins, Nashville. Tenn.; ; Carl F. Schmidt, Philadelphia; Erwin W. Straus, Lexington, Ky.; Howard C. Taylor Jr., New York; Joseph F. Volker, Boston; William M. Wallace, Boston, and Friedrich Wassermann, Chicago.

Survey of Multiple Sclerosis.—A sixteen page manual of information on the diagnosis and treatment of multiple sclerosis, prepared by the National Multiple Sclerosis Society, was distributed to about 76,000 physicians in the United States during May. The manual, published in full in the Nov. 1, 1947 issue of THE JOURNAL, gives the latest information on rehabilitation and symptomatic treatment. A letter was enclosed asking physicians to inform the society of the number of multiple sclerosis patients in their care. These numerical data will be valuable as an initial fact-finding effort preceding a national survey on the prevalence of the disease in the United States. National Multiple Sclerosis Society will soon undertake this survey with the advice and cooperation of the U. S. Public Health Service.

ALASKA

Crippled Children to Be Treated in Chicago.—Twenty-four children from the Alaskan Crippled Children's Service in need of specialized medical care and hospitalization will be treated this year at the Home for Destitute Crippled Children, a unit of the University of Chicago Clinics. The project, undertaken by the home to alleviate the suffering of the most difficult and complicated cases among Alaska's orthopedic patients, will make possible medical care and hospitalization for 2 children each month. The Home for Destitute Crippled Children was founded in 1891 and for many years has been affiliated with the University of Chicago.

FOREIGN

International Congress of Otolaryngology.—The British Association of Otolaryngologists is organizing the Fourth International Congress of Otolaryngology to be held in London, July 17-23, 1949. There will be further meetings, for those interested, at Oxford, Cambridge and Edinburgh on July 25-26. The secretaries of the national otolaryngological societies have been asked to send a list of their members for individual notification. Should any association not receive this letter, its secretary should communicate with the General Secretary, Mr. F. C. W. Capps, F.R.C.S., 45, Lincoln's Inn Fields, London, W. C. 2.

Medical Weeks.—The International Association of Medical Press has organized European conferences and weeks. The Italian Medical Week in Spain will be a series of lectures held by Italian professors and the universities of Zaragoza, Madrid, Barcelona, Valencia, Valladolid and Santiago de Compostella; it will take place in June 1948. The official invitations have been sent from the Spanish universities to the most eminent Italian professors. Reciprocally, a Spanish Medical Week will soon be organized at the University of Bologna in November 1948. The Italian Medical Week at Paris was to have taken place in December 1947 but was postponed because of the political situation in France. An effort will be made to arrange the meeting for June or September, 1948. Professor G. Caronia, rector of Rome University, has been appointed chief of the Italian delegation. Professor Caronia has already been invited by the French government in Paris to contact the *doyens* of the Medical Faculty of the University of Paris about the organization of the meeting. French Medical Week at Rome will be organized with the cooperation of the rector of Rome University, Professor Caronia, and the *doyens* of the faculty of medicine and pharmacy of the University of Paris.

CORRECTIONS

Internship and Residency Number —The following corrections pertain to the Internship and Residency number of THE JOURNAL published May 1, 1948.

Dr. B. D. Jay is chief of the Radiology service, Charles S. Wilson Memorial Hospital, Johnson City, N. Y., instead of Dr. E. M. Jones (page 79).

Data regarding St. Mary's Hospital, Brooklyn (page 57), are revised as follows: Chief of service, Dr. Henry J. Goubeaud Jr.; inpatients treated, 2,617; number of outpatient visits, 5,343; deaths on service, 7; number of autopsies, 1; assistant residents, 2; residents, 1; service begins, July 1; length of service, 2 years; minimum stipend per month, $50.

Data regarding Edward J. Meyer Memorial Hospital, Buffalo (page 86), are revised as follows: Dr. John D. Stewart, chief; inpatients treated, 147; deaths on service, 23; number of autopsies, 13; residencies offered, 2 starting July 1; length of service, 3 years; minimum stipend per month, $100.

Marriages

JAMES EDWARD SEGERSON to Miss Margaret Isabel Crowley, both of Rochester, N.Y., May 1.

AUGUSTUS LYNN BAKER Jr., Dover, N.J., to Miss Eleanor Jean Black at Mountain Lake, April 24.

PETER RANDALL, Philadelphia, to Miss Rose Gordon Johnson of Baltimore, May 1.

SHEROD M. BILLINGTON, Seattle, to Miss Carol Dore, of Redmond, Wash., April 17.

CHARLES LEONARD SMITH, Spartanburg, S.C., to Miss Bobbie Jean Love of Asheville, N.C., April 3.

DONALD ROY PRATT to Dr. ARLENE MARJORIE MANN, both of San Francisco, April 7.

JACK SPENCER, Portland, Maine, to Mrs. Charlotte Nolan Crawford of Bryn Mawr Pa., in March.

CHARLES GLENN SAWYER, New Bern, N.C., to Miss Elizabeth Gaston Ivey of Albemarle, April 24.

OWEN FLOYD HUGHES to Miss Betty Joyce Blalock, both of Birmingham, Ala., in April.

MICHAEL V. GILBERTI, Aliquippa, Pa., to Miss Grace Anne Chase of Coatesville, April 24.

Deaths

Edward Joseph O'Brien Jr., ⊕ Newton, Mass.; born in Chelsea, Mass., in 1888; Tufts College Medical School, Boston, 1912; specialist certified by the American Board of Urology, Inc.; member of the New England Obstetrical and Gynecological Society and of the American Urological Association; fellow of the American College of Surgeons; at one time college football referee; affiliated with St. Elizabeth's Hospital, Brighton, Somerville (Mass.) Hospital, State Infirmary, Tewksbury, Metropolitan State Hospital, Waltham, Charles Choate Memorial Hospital, Woburn, and the Cambridge City Hospital, where he died February 15, aged 60, of coronary thrombosis.

Thomas Christopher Patterson, Lisbon, N. D.; born in Grafton, Ontario, Canada, Jan. 9, 1864; Trinity Medical College, Toronto, Canada, 1889; member of the American Medical Association; formerly alderman, member of the park commission, president of the county board of health and member of the school board; regimental surgeon for the first North Dakota infantry regiment serving with it on the Mexican border in 1916 and 1917; served during World War I; commandant of the North Dakota Soldiers' Home; died in the Veterans Administration Center, Fargo, February 22, aged 84, of carcinoma of the stomach.

Frederick Walter Rice, New York; born in Winn, Maine, March 25, 1880; Columbia University College of Physicians and Surgeons, New York, 1906; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons; formerly on the faculty of the New York University College of Medicine; served during World War I; affiliated with Holy Angels Hospital in Teaneck, N.J., Margaret Hague Memorial Hospital in Jersey City, Norwalk (Conn.) General Hospital, Bellevue and Doctors hospitals; died March 30, aged 68.

Arthur Ferdinand Cooper ⊕ Memphis, Tenn.; born Aug. 26, 1881; Vanderbilt University School of Medicine, Nashville, 1904; associate professor of medicine at the University of Tennessee College of Medicine; past president of the Memphis-Shelby Counties Medical Society; formerly secretary of the Mid-South Post Graduate Medical Assembly; served as editor of the *Memphis Medical Journal;* affiliated with John Gaston Hospital, Methodist Hospital, Veterans Administration Hospital and Baptist Memorial Hospital, where he died January 7, aged 66, of pneumonia.

Perry Watson Miles ⊕ Danville, Va.; born in Mathews, Va., Feb. 9, 1883; University College of Medicine, Richmond, 1908; formerly vice president of the Medical Society of Virginia; served as president of the Danville-Pittsylvania Academy of Medicine; member and chairman of the school board, for many years resident physician for the Southern Railway; chief of staff of the Danville Memorial Hospital; member of the draft board during World War II; died in Johns Hopkins Hospital, Baltimore, February 21, aged 65, of cerebral hemorrhage.

Rosier Davis Dedwylder, Cleveland, Miss.; born in 1882; University of Alabama School of Medicine, University, 1907; member of the American Medical Association; gave up his private practice in 1912 to work with the state board of health and the Rockefeller Foundation in a study of hookworm in the South; subsequently carried out investigation of malaria and malaria control; since 1920 director of the Bolivar County Health Department; died in the City Hospital February 20, aged 65, of coronary thrombosis.

Thomas McSwiney Barrett ⊕ Emsworth, Pa.; born in Emsworth, Pa., Dec. 31, 1881; Western Pennsylvania Medical College, Pittsburgh, 1906; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association and the Association of Military Surgeons of the United States; served during World War I; at various times associated with the Dixmont (Pa.) State Hospital, Suburban General Hospital, Bellevue, Veterans Administration Hospital in Knoxville, Iowa, and St. Francis Hospital in Pittsburgh, where he died March 27, aged 66, of carcinoma of the colon.

Thomas Edwin Neill ⊕ Washington, D. C.; Georgetown University School of Medicine, Washington, 1908; formerly on the faculties of the Georgetown University School of Medicine and the George Washington University School of Medicine; served during World War I; past president of the Medical Society of the District of Columbia and the Clinico-Pathological Society of Washington; formerly on the staffs of Emergency Hospital and Garfield Memorial Hospital, where he died February 22, aged 69, of coronary occlusion.

David Benjamin Martinez ⊕ Slidell, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1922; fellow of the American College of Surgeons; formerly associate professor of obstetrics at the University of Pittsburgh School of Medicine and on the staffs of the Magee and Presbyterian Hospitals in Pittsburgh; served on the staff of the New Biloxi (Miss.) Hospital; died in the Touro Infirmary, New Orleans, February 26, aged 49.

Michael Depta ⊕ Pittsburgh; born in Mount Pleasant, Pa., on May 8, 1889; University of Pittsburgh School of Medicine, 1917; assistant professor of laryngology and rhinology at his alma mater; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; served during World War I; affiliated with the Pittsburgh Hospital, Presbyterian Hospital and St. Francis Hospital, where he died February 2, aged 58, of coronary thrombosis.

Percival C. Barnes, University City, Mo.; St. Louis College of Physicians and Surgeons, 1906; member of the American Medical Association; died February 27, aged 73, of leukemia.

Charles Worcester Beaman, Cincinnati; Eclectic Medical Institute, Cincinnati, 1903; formerly on the faculty of his alma mater; served during World War I; died February 25, aged 67, of aortic aneurysm.

Joseph Napoleon Boyer Jr., Springfield, Mass.; Harvard Medical School, Boston, 1899; served during World War I; died in the Veterans Administration Hospital, Northampton, February 26, aged 72, of coronary thrombosis.

Robert Lee Bushart ⊕ Fulton, Ky.; University of Tennessee Medical Department, Nashville, 1901; past president of the Hickman and Fulton Counties Medical Society; affiliated with the Fulton Hospital; died February 22, aged 72, of coronary thrombosis.

Frank Hough Carber, New York; Columbia University College of Physicians and Surgeons, New York, 1912; formerly a fellow in medicine at the Mayo Foundation in Rochester, Minn.; served during World War I; at one time chief examiner for the Life Extension Institute; medical director of the Mutual Life Insurance Company; died February 28, aged 62, of heart disease.

Travis Carroll, Cincinnati; University of Louisville (Ky.) Medical Department, 1883; Medical College of Ohio, Cincinnati, 1891; died February 24, aged 86, of chronic myocarditis.

Sherman Cook, Attica, Ohio; Cleveland Medical College, Homeopathic, 1897; died in the Bucyrus City Hospital in Bucyrus February 19, aged 76, of pernicious anemia.

William J. Cummings, Alvarado, Texas; University of Texas School of Medicine, Galveston, 1909; past president of the Johnson County Medical Society; city health officer of Alvarado and local physician for the Missouri, Kansas and Texas Railroad; served as member of the school board and as alderman; died in a hospital at Fort Worth, February 11, aged 63, of pneumonia.

Martin Dalton, Fenton, Mo.; Marion-Sims College of Medicine, St. Louis, 1896; member of the American Medical Association; a director and one of the founders of the Farmers and Merchants' Bank; died February 28, aged 79, of pneumonia.

Spencer Cornelius Dickerson ⊕ Chicago; Rush Medical College, Chicago, 1901; formerly field health officer; served in France during World War I; on the staff of the Provident Hospital; died in the Albert Merritt Billings Hospital February 25, aged 77, of heart disease.

Boyd Dodson ⊕ Wilkes-Barre, Pa.; Jefferson Medical College of Philadelphia, 1889; past president of the Luzerne County Medical Society; for many years member of the board of education; member of the staff of the Wilkes-Barre General Hospital; died March 19, aged 80, of acute dilatation of the heart.

Benjamin Adoneram Doggett ⊕ Norfolk, Va.; Medical College of Virginia, Richmond, 1915; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; president elect of the Norfolk County Medical Society; affiliated with the Norfolk General Hospital, where he died February 27, aged 55, of subarachnoid hemorrhage.

Franz Gill Edwards ⊕ Waldport, Ore.; Harvard Medical School, Boston, 1923; served during World War I; director of the Waldport Community Hospital; died February 2, aged 52, of pulmonary and cerebral hemorrhage.

Emily Hartman Emery, Vallejo, Calif.; Hahnemann Hospital College of San Francisco, 1897; at one time health officer of Emeryville; affiliated with the Juvenile Detention Home in Oakland; died February 21, aged 81, of carcinoma.

Thomas Luther Goodnight ⊕ Caldwell, Texas; University of Louisville (Ky.) Medical Department, 1913; past president of the Burleson County Medical Society; county health officer; served during World War I; member of the Selective Service Board during World War II; local physician and surgeon for the Santa Fe and Southern Pacific Railroads; died February 9, aged 59, of multiple myeloma.

Lawrence E. Heiges, Lompoc, Calif.; Northwestern University Medical School, Chicago, 1904; served as mayor of the city of Lompoc; formerly member of the Santa Barbara County Planning Commission; on the courtesy staff of the Santa Barbara Cottage Hospital in Santa Barbara; on the honorary retired staff of the Lompoc Hospital, where he died February 15, aged 73, of acute hepatitis.

Carrie S. Staines Kellogg ⊕ Fenwick, Mich.; American Medical Missionary College, Battle Creek, Mich.; and Chicago, 1899; for many years member of the staff of the Battle Creek Sanitarium in Battle Creek, member of the Michigan State Medical Society; died February 16, aged 80, of cerebral hemorrhage.

John William Ledbury ⊕ Uxbridge, Mass.; College of Physicians and Surgeons, Baltimore, 1905; an Affiliate Fellow of the American Medical Association; died February 20, aged 72.

Samuel Johnston McNeill ⊕ Chicago; Rush Medical College, Chicago, 1903; past president of the Northshore Branch of the Chicago Medical Society; at one time on the faculty of his alma mater; formerly associated with Augustana Hospital; died February 16, aged 73, of cerebral hemorrhage.

Joseph Henry Mitchell, Dillwyn, Va.; Baltimore Medical College, 1895; died in the Johnston-Willis Hospital, Richmond, February 11, aged 84.

John Archibald Nelson, San Francisco; University of California Medical School, San Francisco, 1892; died February 21, aged 82, of bronchopneumonia.

Manning Lionel Nelson, North, S. C.; Medical College of the State of South Carolina, Charleston, 1909; member of the American Medical Association; affiliated with the South Carolina Baptist Hospital in Columbia, where he died February 21, aged 64, of coronary thrombosis.

John Thomas Padgham, Grinnell, Iowa; State University of Iowa College of Medicine, Iowa City, 1909; member of the American Medical Association; for many years treasurer of the Powshiek County Medical Society; served on the school board; affiliated with St. Francis and Community Hospitals; died February 18, aged 71, of congestive heart failure.

Mary Elizabeth Beasley Poket, Hamilton City, Calif.; College of Physicians and Surgeons of San Francisco, 1903; died in the Enloe Hospital, Chicago, February 17, aged 77.

George Washington Potts, Los Angeles; Jefferson Medical College of Philadelphia, 1884; died February 21, aged 85, of cerebral hemorrhage.

Albert Lee Roberts, Tuscaloosa, Ala.; University of Tennessee College of Medicine, Memphis, 1918; specialist certified by the American Board of Psychiatry and Neurology, Inc.; served during World Wars I and II; affiliated with the Veterans Administration hospitals in Gulfport, Miss., and Tuscaloosa; died February 20, aged 59, of coronary thrombosis.

Abraham Harry Roller ⊕ Bristol, Vt.; University of Vermont College of Medicine, Burlington, 1935; served as secretary of the Addison County Medical Society; affiliated with Mary Fletcher Hospital, the Bishop De Goesbriand Hospital in Burlington and Porter Hospital, Middlebury; died February 12, aged 38, of coronary disease.

Homer Rogers, Bakersfield, Calif.; University of Southern California College of Medicine, Los Angeles, 1897; served during World War I; affiliated with the Kern General Hospital, where he died February 16, aged 72, of hypertension and heart disease.

Lonzo O. Rose, Parkersburg, W. Va.; College of Physicians and Surgeons, Baltimore, 1901; member American Medical Association and the Radiological Society of North America, Inc.; chemist and bacteriologist for the city of Parkersburg for many years; served as president of the Academy of Medicine of Parkersburg; died in Cincinnati February 23, aged 70, of hypostatic pneumonia.

David Rosner, New York; Long Island College Hospital, Brooklyn, 1905; died January 28, aged 66.

Charles N. Schaefer ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1904; member of the Radiological Society of North America, Inc.; died February 2, aged 69, of coronary occlusion.

Frederick William Schilling, Louisville, Ohio; Ohio Medical University, Columbus, 1895; died February 20, aged 76.

Walter Sherwood, Brookline, Mass.; Harvard Medical School, Boston, 1896; died February 9, aged 74, of cerebral thrombosis.

James R. Stirrup, Kiowa, Okla.; Gate City Medical College, Dallas, Texas, 1907; died February 27, aged 75, of cerebral hemorrhage.

James Cornelius Sullivan ⊕ Buffalo, University of Buffalo School of Medicine, 1910, fellow of the American College of Surgeons, on the faculty of his alma mater; served during World War I, on the staffs of the Buffalo General, Children's and Deaconess hospitals; died February 2, aged 59, of cerebral hemorrhage.

Elmer Seth Tenney ⊕ Major, U. S. Army, retired, Seattle; Dartmouth Medical School, Hanover, N. H., 1897; entered the medical corps of the regular army in 1919 and retired Sept. 30, 1932; veteran of the Spanish-American War and World War I; died in Madigan General Hospital, Tacoma, January 24, aged 77.

Philip Percy Turner, Clayton, N.J., Jefferson Medical College of Philadelphia, 1897; also a druggist; died February 20, aged 78.

Charles Manley Walters ⊕ Burlington, N.C.; University of Maryland School of Medicine, Baltimore, 1908, died in St. Leo's Hospital, Greensboro, February 18, aged 71, of a skull fracture received in an automobile accident

Cassius M. Clay Walters ⊕ Los Angeles; Rush Medical College, Chicago, 1892; served during World War I; died February 19, aged 78, of hypostatic congestion of the lungs.

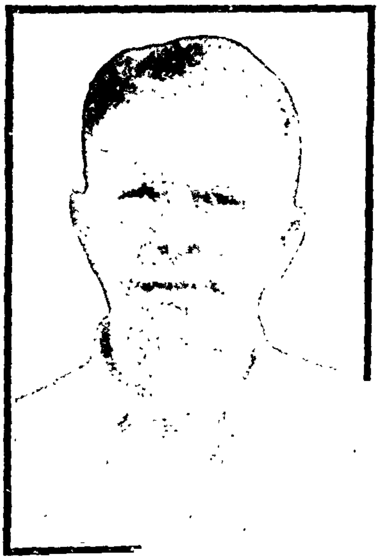
James Pendleton Webb, Durant, Okla.; Birmingham Medical College, 1915; member of the American Medical Association; died February 3, aged 58.

Agnes Ross Wilder ⊕ Atlantic, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1897; affiliated with the Atlantic Memorial Hospital; died February 17, aged 74, of heart disease.

August William Zillman, Keytesville, Mo.; Rush Medical College and Hospital, Chicago, 1897; American Medical Association; died February 12, aged 88.

KILLED IN ACTION

LIEUT. (JG) CLAUDE E. ARNETT JR.
(MC) U.S. NAVY, 1918-1945



COMDR. JAMES DANIEL BOONE
(MC) U.S. NAVY, 1903-1945

CAPT. MAYO W. ALBERT
M.C., A.U.S., 1914-1944

Claude Elias Arnett Jr., Acting Assistant Surgeon, Lieutenant (jg) U.S. Navy, Emporia, Kan.; University of Kansas School of Medicine, Kansas City, 1943; began active duty as lieutenant (jg) in the U.S. Navy in August 1943, serving an internship at the Naval Hospital in San Diego; killed in Iwo Jima Feb. 19, 1945, aged 27.

James Daniel Boone ⊕ Commander, U.S. Navy, Highland, Kan.; Northwestern University Medical School, Chicago, 1930; entered the U.S. Navy on July 1, 1929; interned at the U.S. Naval Hospital in San Diego; on surgical duty at the Canacao Naval Hospital at the time war started; when Manila capitulated he was taken prisoner and interned in Bilibid Prison there; cared for the interned army and navy personnel during the four years he was confined; sent to Japan on the ill-fated prison ship which left Manila on Dec. 13, 1944; awarded a citation posthumously; awarded the Legion of Merit Medal for his courageous work at Canacao and Sangley Point area during the bombings there; died Jan. 23, 1945, aged 42.

Mayo William Albert, Houston, Texas; University of Texas Medical Branch, Galveston, 1940; interned at St. Elizabeth Hospital in Dayton, Ohio; began active duty as a first lieutenant in the medical corps, Army of the United States, in August 1941; promoted to captain in January 1944 left for the European theater of war in the medical unit of a combat battalion attached to the 174 Engineering Regiment; killed in action on the Normandy Beachhead June 6, 1944, aged 30.

Louis Percy Kasman, Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1928; member of the American Medical Association; interned at the Crown Heights Hospital in Brooklyn; began active duty as a captain in the medical corps, Army of the United States, Aug. 16, 1942; promoted to major; killed in action in Germany March 24, 1945, aged 42.

Second Plebiscite on National Health Service

Because of the concessions made by the Minister of Health the British Medical Association has held a second plebiscite of the whole profession on the government plan for a national health service. The result shows that 14,620 doctors approved and 25,842 disapproved. Though there is a large majority for disapproval, it has considerably diminished since the first plebiscite, which showed 40,814 disapproving and only 4,084 approving. Of general practitioners, 9,588 disapproved and 8,639 approved in this second plebiscite, a considerable advance in approval on the first plebiscite. Thus the 13,000 majority of general practitioners, which the British Medical Association laid down as necessary if the profession was to be advised to remain outside the act, was not attained.

The council of the medical association has issued a statement that the members of the profession should recognize that on some fundamental issues they have gained a substancial victory and must now prepare themselves by continued solidarity to strive for improvements by every means at their command. It appeals to those who have grave misgivings to accept the fact that an insufficient number of general practitioners share their view. The minister has appealed to the physicians to cooperate, and time has come for them so to do to the best of their ability, though with unrelenting vigilance. The council has accepted the minister's invitation to enter into discussions on the amending bill and other matters. His attention is being drawn to the large section of the profession still opposed to the national health service, and whose good will is necessary if it is to succeed. The council will report to the representative body that despite insufficiency of the safeguards to the profession's freedoms it should advise physicians to cooperate on the understanding that the minister will continue to negotiate on outstanding matters. The public should be informed that, for reasons outside the control of the medical profession, the new service cannot provide for some time all the improvements promised by the government. And so what at one time seemed a titanic struggle fizzes out in compromise, a typically English ending foretold in previous letters. There are some enlightened persons who regret that the issue of medical socialism was never fought as a matter of principle and that the English people will discover its evils only in the costly school of experience.

Improved Health of the Nation

The remarkable improvement in the health of the nation shown by vital statistics during and after the war continues. At a press conference held in London, the chief medical officer of the Ministry of Health, Sir Wilson Jameson, stated that last winter was the best England ever had as regards national health and that prospects for the coming summer were good. The general death rate for the three months ending March 31 (the worst period of the year) was easily the lowest ever known in England and Wales. The provisional figure was 12.3 deaths per thousand population, compared with a death rate of over 17 in the same period last year, which was one of the worst quarters ever known. The nearest approach in recent times to the remarkable figure of 12.3 was 13.2 in the first quarter of 1943. The number of deaths from influenza in the first quarter of 1948 was 644, against 2,796 in 1947 and 4,242 in 1946. This was the lowest figure recorded for that period.

Dr. W. H. Bradley, senior medical officer of the Ministry of Health, said that as a result of poliomyelitis last year the country was left with 3,000 cripples, but 2 of every 3 would overcome their handicap and live normal, useful lives. The epidemic was three times larger than any that had occurred previously in England and Wales. There were 7,800 cases and 700 deaths (9 per cent of the confirmed cases). Only one third of the patients were under 5 years of age. Eighteen per cent of those who died were between the ages of 35 and 45. The younger patients had a much better chance of survival than those in the upper age groups.

Sir William Jameson referred to the success of the immunization campaign against diphteria. Last year the number of deaths was 244. For every 10 children who died before the campaign for immunization only 1 dies now. The number of children who had diphtheria last year was 55,000 fewer than in 1938.

Students' International Clinical Congress

An international Clinical Congress of Medical Students, the first of its kind, will be held in Britain in July under the auspices of the British Medical Students' Association. So far one hundred and thirty delegates from thirty different countries have accepted the British invitation. A program of lectures, visits and ward rounds in various teaching hospitals, discussions, and entertainment for the visitors have been arranged to take place in the universities of London, Oxford and Birmingham. The organizational expenses have been met by grants from the British Medical Association and the International Union of Students. But the response to invitations shows that delegates from many countries have difficulty in meeting the necessary expense of attending. The British Council has generously agreed to cover the fee to the congress for a number of delegates, but many countries will have to remain unrepresented unless further support is forthcoming. An appeal has therefore been made by the honorary president of the congress, Professor J. A. Ryle, the president of the British Medical Students Association, S. Drancz, and the chairman of the Congress Organizing Committee, H. E. Reiss, for contributions from individual members of the public or from societies which have at heart the furtherance of friendship and understanding of students from all over the world to make the congress truly international in character. Contributions will be received by the Treasurer, Students' International Congress, British Medical Students Association, B.M.A. House, Tavistock Square, London, W. C. 1.

TURKEY

Ankara, May 18, 1948.

Turkey's Malaria Campaign

Although malaria control work has been under way twenty-five years, malaria remains the most prevalent of all preventable diseases in Turkey. At present there are malaria control administrative units in 52 of the 63 provinces, in 13,317 of the more than 40,000 villages and in 301 of the 472 districts. The control work has been divided into 40 zones where 293 specialist physicians, 1,117 malaria sanitary inspectors, 5 sanitary engineers and 2 technicians are employed. Every zone has a director, two bacteriologists and a number of physicians. Whether a region is to be included in the campaign zone depends on the spleen and blood index; if it is not alarming responsibilities are delegated to health officers or municipalities. The zones are under supervision of three specialist district health officers. All graduating physicians are required to spend three months at the Adana Malaria Institute, where they take courses in malariology, parasitology, entomology, hematology and malaria pathology and engage in field work. A special law requires every able bodied peasant to give once a year five days of unpaid work on swamp draining. Serious cases of malaria are treated at the three twenty-bed ambulatory hospitals. This has greatly reduced the mortality rate. All treatments and medicines, quinine, quinacrine, pamaquine and others, are free and paid for from the government budget. Patients who cannot take quinacrine are given quinine; children are given quinine ethylcarbonate or quinine carbonate. The antimosquito work is carried on all the year round. Once a week habitations and stables are sprayed with a 5 per cent solution of DDT. Breeding places are sprayed with DDT diluted with crude oil. In some places Paris green or "velsicol" is used.

In his 1947 report to the ministry of Health, Dr. Seyfeddin Okan, director general of the malaria campaign division, stated that there has been no malaria epidemic in any of the malaria zones and that new cases of malaria have been few.

The climate in Turkey varies. While there are still heavy snows in the Northeast, mosquitoes are coming out in the subtropic South. The species encountered in Anatolia are Anopheles maculipennis, A. bifurcatus, A. algeriensis, A. hyrcanus, A. nigripens, A. eletus and A. superpictus. Though one type is generally confined to a certain region, one or two other types are often encountered in the same place, and in the Menderes River basin all seven types are present, though A. maculipennis and A. eletus are in the majority. However, in the Seyhan and Ceyhan basin A. maculipennis are rare and few. In the Sakarya plain A. maculipennis predominate; A. eletus are few and are found only in restricted areas. Although in the villages in the environs of Istanbul A. maculipennis is the only species and is present in great numbers, in one village of the same environs, the village of Kucuk Cekmece, at the border of a lake, A. eletus are also present.

According to research in 1934-1935 by Dr. Mahmud Sabit Akalin, director of the Adana Malaria Institute (1930-1936) in the malarial regions of Western Anatolia, the domestic anopheles are the maculipennis type, A. eletus and A. superpictus. A. bifurcatus are semidomestic; A. hyrcanus, A. algeriensis, and A. nigripens are wild and prefer to feed on animals rather than on human blood. Of the A. maculipennis variety there are A. messeae, A. melanoon and A. typicus. In some parts of Anatolia where many persons suffer from chronic malaria there are no malaria epidemics; this bears out that the anopheles in those regions are of the zoophile and anthropophile types. Twenty years of research indicate that in Anatolia epidemics of malaria are spread by A. superpictus and eletus, and it is the latter in particular that spreads malaria in the Seyhan and Ceyhan plain. In the rice plantation districts of Asia Minor where three types of A. maculipennis predominate malaria epidemics are rare; in areas where A. eletus predominate from 30 to 50 per cent of the population is infected. The ten year statistics of the spleen and blood index in the Sakarya plain area indicate that in regions where the index is low A. maculipennis typicus predominate and in regions where the index is high A. eletus predominate.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, May 15, 1948.

Leishmaniasis of the Guinea Pig

Dr. Heitor Medina, of the Biological Institute of Curitiba, Parana, Brazil, described in 1946 for the first time a spontaneous infection of the guinea pig by a parasite of a new species which he called Leishmania enriettii. The original paper presented a study of the infection, which caused the appearance of skin tumors of infiltrative type, with a decided tendency to grow and finally to produce necrosis. In a recent paper a detailed study of the parasite was reported by Drs. Julio Muniz and Medina of the Oswaldo Cruz Institute.

The authors reproduce the disease in all the guinea pigs, by subcutaneous inoculation of material from lesions or from recently isolated cultures; guinea pigs from Europe and the United States were as receptive as those from Brazil. In 25 guinea pigs inoculated with the material it has not been possible to obtain either visceral lesions, as is the case with human and canine kala-azar, or ulcerative lesions of the mucous membranes as in the American tegumentary leishmaniasis. However, new lesions may appear on the skin in regions far from the point of inoculation, such as the forepaws, the ears and the genital organs. By scratching the lesions with its own contaminated nails the animal may cause infections at other points. Death during the infection is due in most cases to the invasion by bacteria. Morphologically the parasite displays peculiarities not yet found in other species of the same genus. Immunologically the guinea pig has only a low capacity of defense against the parasite, as demonstrated by the negative fixation reactions in different periods of the infection, the same results being obtained from cutaneous tests not only with L. enriettii but also with Leishmania brasiliensis antigens. L. enriettii antigen fixes complement strongly in the presence of serums from human subjects with American tegumentary leishmaniasis and causes positive reactions in the same persons when used in cutaneous tests.

Many attempts were made to infect with this species different mammals such as rhesus, hamster (Cricetus auratus), dog, white rat and mouse. Of all these animals, only 1 of 8 hamsters which were inoculated showed, at the end of six weeks, a small crusty formation in the inoculation point (the nasal region). The behavior of L. enriettii in regard to the hamster, rhesus, dog and white mouse, all of them animals susceptible to experimental infection by the species responsible for human leishmaniasis, and its inability to infect man, constitute a biologic difference that separates the organism from the human species.

The great receptivity to the infection shown by the guinea pig and the relatively short period of time in which the lesions appear render L. enriettii a choice material for chemotherapeutic studies. Following this idea the authors succeeded in the treatment and cure of the guinea pig leishmaniasis by antimonial compounds.

Study Miniature Roentgen Examinations

Dr. Heliodoro Costa, radiologist of the Health Center of the Fourth Sanitary District of Rio de Janeiro, published a study about 30,690 miniature roentgen examinations of the chest. This sanitary district is mainly residential in character, and its population includes persons of high as well as low economic condition. Of all the roentgenograms, 1,268 (4.1 per cent) revealed pathologic signs. Among them, 1,081 (3.5 per cent) revealed tuberculous lesions, 951 (3.1 per cent) being of active tuberculosis and 124 (0.4 per cent) of inactive tuberculosis. The remaining 187 pathologic pictures included 138 nontuberculous pulmonary and pleural abnormalities and 49 thoracic abnormalities.

Brief Items

Drs. Hugo B. Firmeza and Zey Bueno, of the Ministry of Labor, have been appointed on the *Committee of Health and Safety of the Work in Mines.* The committee has been constituted to draft regulations to govern the mining industry, embodying the newest developments in hygiene and safety in this field. Dr. E. Magalhães Gomes has been appointed professor of clinical medicine at the University of Rio de Janeiro. Dr. Ernani Lopes resigned the post of director of the Gustavo Riedel Psychiatric Hospital. Dr. I. Cunha Lopes has been appointed to succeed Dr. E. Lopes.

Association of Methylene Blue and Sulfadiazine in Treatment of Blastomycosis

Dr. J. Pellegrino, of the Pharmacological Department, University of Minas Geraes, published a report of his work to test the *influence of methylene blue on the in vitro action of sulfadiazine* on Blastomycosis brasiliensis, the causative agent of South American blastomycosis. As a culture medium he used Sabouraud' glucose to which were added methylene blue in 1:400,000 concentration and sulfadiazine in concentrations from 5 to 40 per cent. The experiments were made with two samples of B. brasiliensis. The hundred and forty culture tubes were kept at room temperature and examined up to the thirty-fifth day after seeding. Dr. Pellegrino found that sulfadiazine in a 5 per cent concentration does not prevent and may even favor the development of the fungus. The inhibiting action of the combined medium is stronger than that of methylene blue alone in the same concentration. Methylene blue does not affect the action of sulfadiazine on the in vitro development of B. brasiliensis in efficient concentrations of the sulfonamide compound. The author strongly suggests the association of methylene blue with the sulfonamide drugs and the specific antimycotic vaccine.

Internal Blastomycosis

Dr. Oswaldo Paulo Forattini reports 2 cases of internal blastomycosis caused by Blastomyces brasiliensis localized in the pancreatic region, without apparent involvement of skin, mucous membranes or the superficial lymph nodes. The clinical picture may lead to the diagnosis of more commonly observed diseases such as neoplasms or tuberculosis. Biopsy will reveal the true nature of the ailment. Both patients were critically ill, but sulfadiazine acted remarkably well, having cured 1 of the patients (working regularly now more than ten months and feeling fine) while the other has improved considerably but is still under treatment.

MADRID

(From Our Regular Correspondent)

May 18, 1948.

Activities of the Neuropsychiatric Clinic

At the Neuropsychiatric Clinic of the Madrid General Hospital, whose present head is Dr. J. J. Lopez Ibor, there was much activity. Last year a course was given on advances in neuropsychiatry, in which the following lecturers spoke: R. Alberca on infections of the nervous system; F. Marco Merenciano on clinical history; J. Germain on clinical psychology; E. Escardo on advances in hypothalamus physiopathology; M. Peraita on avitaminosis and the nervous system, and J. Lopez Ibor on leukotomies and the frontal lobe. This year two courses are being given: one on neurologic and psychiatric examination by Drs. Olivares, Castilla, Leoz, Morillas y Heredia, Turina y Coullant, Urquiza, Guera, Land and Llopis, with intermediate talks by Professor Lopez Ibor; and the other, with Professor Lopez Ibor the only lecturer, on vital anguish and the thymopathic circle (basic principles of a psychosomatic pathology). There are fourteen talks in this course. Professor Ibor starts from the classic descriptions of Westphal's agoraphobia and defines a clinical picture made up of observations falling under different headings in psychiatry. The nuclear part of that entity is constituted by anguish; but, departing from the classic and psychoanalytic descriptions of the anguish neurosis, he does not look on this as such a neurosis--i.e., a state arising from a psychogenic cause or produced reactively--but as an endogenous condition. In studying the symptomatology of "thymopathics" he includes what he calls vital anguish, vertigo characteristic of agoraphobic persons and a series of somatic and vegetative disorders, among which he places disturbances of space and time perception, and these he subjects to preliminary phenomenologic analysis. He points out that in thymopathic sufferers "pathic" space and time are deranged. The vegetative symptomatology is varied and curious: many conditions diagnosed as organic neuroses, the author says, really belong to this thymopathic morbid circle. He draws attention to the surprising association of these psychic conditions with a certain neurologic symptomatology, a fact which had not been pointed out before. Writer's cramp and spastic torticollis are both good examples of this. Vasovagal attacks do not belong to the epilepsy circle either, but to the thymopathic. This set of derangements must be connected with a disorder of the vital stratum of personality, widely conceived, seeing in it instinctive, somatic-visceral and affective components. He does not consider the vital stratum constituted solely by the vital feelings and thinks it better to speak of a "vital structure" than of a "vital stratum." Indeed the disturbances of the vital stratum constitute the "great thymopathic circle" in which the author includes: (*a*) endogenous melancholy and endogenous manias, in which the disturbance occurs around the vital sadness or cheerfulness pole; (*b*) anxious thymopathy, a syndrome in which disturbances occur around the vital anguish pole. (Lopez Ibor believes that vital anguish is not felt at the thought of death but rather at the possibility of the dissolution of personality and worry about this fact); (*c*) diencephalosis, that is vegetative derangements of central origin excluding those which accompany the conditions set forth in the previous paragraphs; and (*d*) certain forms of asthenia so far included in asthenic psychopathy or in constitutional neurasthenia.

These syndromes come on in phases. They are endogenous syndromes with a clear heredity, probably of the dominating type. The author advances the hypothesis that all these derangements may be related to derangements of the diencephalic regulations. This seems to find support in the studies of Hess, which prove the existence of a diencephalic motility with special characters: Hess obtains torticollis conditions in cats by means of diencephalic excitement. Research has proved that the diencephalon enters into the regulation of the psychic functions.

Lopez Ibor's investigations have been extended to the field of therapeutics. He has observed that psychotherapy plays an important, but small, part in anxious thymopathy, since this is a case of somatogenous derangement logically demanding somatic therapeutics. He obtains better results from treatment of patients by vegetative shocks (e.g., by intravenous administration of acetylcholine), and his experience in 1,500 cases supports this criterion.

POSTGRADUATE CONTINUATION COURSES FOR PHYSICIANS

Compiled by the Council on Medical Education and Hospitals
for the Period July 1, 1948 to January 15, 1949

Table of Contents

Subject Page
Allergy 719
Anatomy 719
Anesthesiology 720
Arthritis 721
Bacteriology 721
Basic Sciences 722
Biochemistry 722

Postgraduate Courses for Practicing Physicians—July 1, 1948 to January 15, 1949

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
	ALLERGY		
Cook County Graduate School of Medicine 427 S. Honore St., Chicago	Allergy, One Day Each Week	10 weeks, part time Oct. 1948	$125.00
	One Month Personal Course in Allergy (2 of these courses under different instructors)	1 month, full time Every month	200.00
	Six Months Personal Course in Allergy (2 of these courses under different instructors)	6 months, full time By appointment	500.00
Wayne University College of Medicine, 1516 St. Antoine St., Detroit, Mich. At: City of Detroit Receiving Hospital	Allergy Clinic and Conference	12 weeks, part time Sept. 20-Dec. 11, 1948	25.00
	Allergy Clinic and Conference	12 weeks, part time Dec. 13, 1948-Mar. 19, 1949	25.00
Joint Committee on Post-Graduate Education, Long Island College of Medicine, Medical Society of the County of Kings and Academy of Medicine of Brooklyn, 1313 Bedford Avenue, Brooklyn 16 At: Beth El Hospital	Allergy	8 weeks, part time, Oct. 1948	30.00
At: Kings County Hospital	Allergy	8 weeks, part time, Oct. 1948	20.00
American Academy of Allergy, 60 E. 58th St., New York At: Chicago	Orientation Course in Allergy	5 days, full time, Oct. 18-22, 1948	40.00
Columbia University College of Physicians and Surgeons, 630 W. 168th St., New York 32 At: Mount Sinai Hospital	Allergy in Children (Pediatrics PM-31)	1½ months, part time, Oct. 15-Dec. 3, 1948	30.00
	Allergy (Medicine PM-31)	6 weeks, part time, Oct. 5-Nov. 30, 1948	40.00
At: Roosevelt Hospital	Clinical Allergy (Medicine PM-81)	2 weeks, full time, Nov. 8-20, 1948	120.00
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St. New York	Allergy	2 months, part time, Tuesdays - arranged	50.00
New York Post-Graduate Medical School, 303 E. 20th St., New York 3	#302-Allergy	Part time, Fridays Jan. 7-Feb. 25, 1949	25.00
	#331-Allergy	3 weeks, full time, Nov. 4-24, 1948	200.00
	#423-Allergy for Pediatricians[1]	5 days, full time, Oct. 4-8, 1948	75.00
University of Pittsburgh School of Medicine, Bigelow Boulevard, Pittsburgh, Pa. At: School of Medicine and Montefiore Hospital	Orientation Course in Allergy	10 Thursday afternoons Beg. Sept. 2, 1948	50.00
Graham-Thomas Clinic, 201 W. Franklin St., Richmond 20, Va.	Course of Training in Clinical Allergy	12 months, July 1, 1948, full time	None
	ANATOMY		
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago 12	Surgical Anatomy on the Cadaver	1 day each week for 10 weeks, part time, Oct. 1948	125.00
	Two week Course, Surgical Anatomy and Clinical Surgery	July 6, Aug. 16, Sept. 27, Oct. 25 and Nov. 22, 1948, full time	150.00

Postgraduate Courses for Practicing Physicians—July 1, 1948 to January 15, 1949—Continued

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
	ANATOMY—Continued		
University of Louisville School of Medicine, 101 West Chestnut St., Louisville 2, Ky. and Kentucky State Medical Association, 620 South Third Street, Louisville 2, Ky. At: Louisville General Hospital	Surgical Anatomy	Throughout the year - Thursdays, part time Except during July and August, 1948	Not given
University of Maryland School of Medicine, Lombard and Greene Streets, Baltimore 1	General Anatomy "A"	Arranged	Arranged according to time
	Surgical Anatomy "B"	2 days a wk.-3 hrs. a day Second Semester (1948) of school year	150.00
Harvard Medical School, Courses for Graduates, 25 Shattuck St., Boston 15	Surgical Anatomy[2]	8 weeks, half time Sept. 7-Oct. 30, 1948	200.00
Tufts College Medical School, Postgraduate Division 30 Bennet Street, Boston 11 At: Ziskind Research Laboratory, New England Medical Center, Boston	Surgical Anatomy[1,3]	8 weeks, part time Nov. 1-Dec. 24, 1948	200.00[4] 5.00[5]
Wayne University College of Medicine, 1516 St. Antoine St., Detroit, Mich.	Evolution of Human Body	12 weeks, Sept. 20-Dec. 11, 1948	25.00
	Human Inheritance	12 weeks, part time Sept. 20-Dec. 11, 1948	25.00
	Surgical Anatomy	24 weeks, part time, Dec. 13, 1948-June 18, 1949	70.00
University of Minnesota Medical School, Department of Postgraduate Education, Minneapolis 14 At: Center for Continuation Study	Review Course in Gross Anatomy	2 months, full time, Approx. July 1 to Sept. 8, 1948	150.00[4] 10.65[6]
Joint Committee on Post-Graduation Education, Long Island College of Medicine, Medical Society of the County of Kings and Academy of Medicine of Brooklyn, 1313 Bedford Avenue, Brooklyn 16	Manikin	8 weeks, part time, Oct. 1948	30.00
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St., New York 29	Anatomy of the Abdomen	100 hours, arranged	150.00
	Anatomy of the Thorax	100 hours, arranged	150.00
	Anatomy of the Urogenital System	130 hours, arranged	300.00
	Anatomy for the Orthopedic Surgeon	100 hours, arranged	150.00
	Applied Anatomy for the Anesthetist	125 hours, arranged	275.00
	Applied Anatomy for the General Surgeon	250 hours, arranged	375.00
	Applied Anatomy for the Otolaryngologist	150 hours, arranged	275.00
New York Polyclinic Medical School and Hospital, 345 W. 50th St., New York 19	Head and Neck Dissection	6 weeks, part time, arranged	150.00
New York Post-Graduate Medical School, 303 E 20th St., New York 3	General Anatomy	8 weeks, part time, arranged	100.00
	Surgical Anatomy of the Abdomen	Part time and full time - 12 weeks, 16 weeks and 8 weeks, arranged	150.00[7] 200.00[8] 225.00[9]
	Surgical Anatomy of the Female Pelvis	12 weeks, part time, arranged	150.00
	Surgical Anatomy of the Head and Neck	Part time and full time - 12 weeks, 16 weeks and 8 weeks, arranged	150.00[7] 200.00[8] 225.00[9]
	Surgical Anatomy of the Musculo-Skeletal System	Part time - 12 weeks and 16 weeks, arranged	150.00[7] 200.00[8]
	Surgical Anatomy of the Thorax and its Viscera	12 weeks, part time, arranged	150.00
	#241-Surgical Anatomy as Applied to Operative Gynecology[1]	Part time, arranged	200.00
	#522-Functional Anatomy in Relation to Orthopedics	Part time, Sept. 20-Oct. 1, 1948	75.00
New York University College of Medicine, 477 First Avenue, New York 16	General Anatomy	8 weeks, part time, arranged	100.00
	Surgical Anatomy of the Abdomen	Part time - 12 weeks, 16 weeks and 8 weeks, arranged	150.00[7] 200.00[8] 225.00[9]
	Surgical Anatomy of the Female Pelvis	12 weeks, part time, arranged	150.00
	Surgical Anatomy of the Head and Neck	Part time - 12 weeks, 16 weeks and 8 weeks, arranged	150.00[7] 200.00[8] 225.00[9]
	Surgical Anatomy of the Musculo-Skeletal System	Part time - 12 weeks, and 16 weeks, arranged	150.00[7] 200.00[8]
	Surgical Anatomy of the Thorax and its Viscera	Part time, 12 weeks, arranged	150.00
Western Reserve University School of Medicine, 2109 Adelbert Road, Cleveland 6, Ohio	Postgraduate Applied Anatomy, Dissection and Lectures	5 afternoons weekly for 2 to 6 months, Oct. 1, 1948 to April 30, 1949	70.00[10]
	ANESTHESIOLOGY		
Graduate Division of the School of Medicine, University of Southern California, Los Angeles 7 At: Los Angeles County General Hospital	Course No. 754 - Anesthesia	12 weeks, part time, Sept. 1948	50.00

Postgraduate Courses for Practicing Physicians—July 1, 1948 to January 15, 1949—Continued

ANESTHESIOLOGY—Continued

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago 12	Personal Course in Ether and Nitrous Oxide (Inhalation) Anesthesia	1 month, full time, every month	125.00
	Personal Course in Ether, Nitrous Oxide, Ethylene and Cyclopropane (Inhalation) Anesthesia	1 month, full time, every month	200.00
	Personal Course in Spinal and Intravenous Anesthesia	2 weeks, full time, every two weeks	150.00
	Two Week Personal Course in Endotracheal Anesthesia	2 weeks, full time, every two weeks	150.00
University of Louisville School of Medicine, 101 West Chestnut Street, Louisville 2 and Kentucky State Medical Association, 620 S. 3rd St., Louisville 2 At: Louisville General Hospital	Anesthesiology	1 week, full time, Fall of 1948	Not Given
	Anesthesiology (Clinical Anesthesia)	Daily, part time, arranged	Not Given
Tufts College Medical School, Postgraduate Division, 30 Bennet St., Boston 11 At: Boston City Hospital	Anesthesiology II	1 month, part time, arranged	60.00[4] 5.00[5]
	Anesthesiology III[1]	6 months, full time, arranged	300.00[4] 5.00[5]
Wayne University College of Medicine, 1516 St. Antoine St., Detroit, Mich.	Anesthesia Theory and Practice	12 weeks, part time, every quarter	15.00
Columbia University College of Physicians and Surgeons, 630 W. 168th St., New York 32 At: Mount Sinai Hospital	Diagnostic and Therapeutic Nerve Blocking (Anesthesia PM-30)[1]	1 month, part time, Oct. 19-Nov. 19, 1948	50.00
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St., New York 29	Clinical Anesthesiology	3 months, full time, arranged	200.00
	Division of Graduate Studies, Basic Medical Sciences-Surgery, Medicine, Obstetrics & Gynecology, Pediatrics, Radiology, Urology, Otolaryngology, Pathology, Anesthesiology	9 months, Oct. 1948	600.00
New York Polyclinic Medical School and Hospital, 345 W. 50th St., New York 19	Anesthesia	3 months, full time, Oct. 1, 1948	300.00
	Applied Anesthesia	3 months, full time, Oct. 1, 1948	300.00
	Applied Anesthesia	3 months, full time, Jan. 2, 1949	300.00
New York Post-Graduate Medical School, 303 E. 20th St., New York 3	#942-Anesthesia[1]	2 weeks, full time, Arranged	125.00 65.00[11]
New York University College of Medicine, 477 First Avenue, New York 16 At: N.Y.U. College of Medicine and Bellevue Hospital	Anesthesiology	6 months, full time, *beginning Oct. 4, 1948*	500.00
	Anesthesiology Regional	2 weeks, full time, Sept. 7-18, 1948	200.00
Graduate School of Medicine, University of Pennsylvania, 237 Medical Laboratories, Philadelphia 4	Segmental Neuralgias; Relief by Regional Anesthesia	3 weeks, part time, 1st of each month, beginning October, 1948	200.00

ARTHRITIS

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
Joint Committee on Post-Graduate Education, Long Island College of Medicine, Medical Society of the County of Kings and Academy of Medicine of Brooklyn, 1313 Bedford Ave., Brooklyn 16 At: Jewish Hospital	Arthritis	8 weeks, part time, October, 1948	30.00
New York Post-Graduate Medical School, 303 E. 20th St., New York 3	#301-Arthritis and Allied Rheumatic Disorders	Tuesdays, part time, Jan. 4-Feb. 15, 1949	45.00
	#330-Arthritis and Allied Rheumatic Disorders	5 days, full time, Oct. 25-29, 1948	55.00
New York University College of Medicine, 477 First Ave., New York 16 At: Bellevue Hospital	Arthritis and Rheumatic Disorders	6 weeks, part time, Oct. 4-Nov. 11, 1948	100.00

BACTERIOLOGY

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
Wayne University College of Medicine, 1516 St. Antoine St., Detroit, Mich.	Antibiotic Substances	12 weeks, part time, Sept. 20-Dec. 11, 1948	15.00
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St., New York 29	Bacteriology	3 months, half time, arranged	100.00
	Immunology	6 weeks, half time, arranged	50.00
	Parasitilogy	6 weeks, half time, arranged	75.00
New York Polyclinic Medical School and Hospital, 345 W. 50th St., New York 19	Practical Laboratory Instruction in Pathology and Bacteriology	Arranged	Arranged

ELECTROCARDIOGRAPHY--Continued

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St., New York 29	Electrocardiography	2 weeks, part time, October 1948	100.00
New York Polyclinic Medical School and Hospital, 345 W. 50th St., New York 19	Electrocardiographic Interpretation	2 weeks, part time, arranged	75.00
New York Post-Graduate Medical School, 303 E. 20th St., New York 3	*345-Electrocardiography	5 days, full time, Nov. 15-19, 1948	55.00
New York University College of Medicine, 477 First Ave., New York 16	Electrocardiography	16 weeks, part time, Oct. 7, 1948-Jan. 20, 1949	75.00
At: Bellevue Hospital (4th Div.)	Practical Electrocardiography for the Practicing Physician	6 weeks, part time, Oct. 6-Nov. 9, 1948	65.00
At: Beth Israel Hospital	Electrocardiography	12 weeks, part time, Sept. 30-Dec. 16, 1948	40.00

ELECTROENCEPHALOGRAPHY

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
Columbia University College of Physicians and Surgeons, 630 W. 168th St., New York 32 At: Columbia-Neurological Institute	Clinical Electroencephalography and Electromyography (Neurology PM-2)[1]	Any three months between Oct. 1, 1948 and March 31, 1949, full time	150.00
At: Mount Sinai Hospital	Clinical Electroencephalography (Neurology PM-33)[1]	3 months, part time, Oct. 7, 1948-Jan. 20, 1949	60.00
Graduate School of Medicine, University of Pennsylvania, 237 Medical Laboratories, Philadelphia 4 and Pennsylvania Mental Hygiene Institute and Hospital for Nervous and Mental Diseases	Electroencephalography	2 or 4 weeks, as arranged	200.00 300.00

ENDOCRINOLOGY

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
Graduate Division of the School of Medicine, University of Southern California, Los Angeles 7 At: Los Angeles County Hospital	Course No. 735 - Endocrinology	12 weeks, part time, October 6, 1948	50.00
Michael Reese Hospital Postgraduate School, 29th St. and Ellis Ave., Chicago 16	Diseases of the Endocrines:- Fundamental Physiology and Diagnostic Methods	10 days, full time Oct. 18-29, 1948	100.00
Harvard Medical School, Courses for Graduates, 25 Shattuck St., Boston 15 At: Massachusetts General Hospital	Pediatric Endocrinology	1 week, full time, Oct. 4-9, 1948	75.00
Wayne University College of Medicine, 1516 St. Antoine St., Detroit, Mich.	Endocrinology	12 weeks, part time, Sept. 20-Dec. 11, 1948	35.00
	Experimental Endocrinology	12 weeks, Sept. 20-Dec. 11, 1948	35.00
Joint Committee on Post-Graduate Education, Long Island College of Medicine, Medical Society of the County of Kings and Academy of Medicine of Brooklyn, 1313 Bedford Ave., Brooklyn 16 At: Beth El Hospital	Endocrine Disorders in Children and Adolescents	8 weeks, part time, October 1948	20.00
At: Jewish Hospital	Disorders of the Endocrine System	6 weeks, part time, October 1948	40.00
	Female Sex Endocrinology	10 weeks, part time, October 1948	20.00
At: Jewish Sanitarium and Hospital for Chronic Diseases	Applied Endocrinology	5 weeks, part time, October 1948	20.00
Columbia University College of Physicians and Surgeons, 630 W. 168th St., New York 32 At: Mount Sinai Hospital	Endocrinological Diseases (Medicine PM-39)	2 months, part time, Oct. 11-Dec. 6, 1948	30.00
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St., New York 29	Endocrinology	3 weeks, full time, December 1948	150.00
New York Post-Graduate Medical School, 303 E. 20th St., New York 3	*222-Gynecological Endocrinology	24 sessions, part time beginning Oct. 5, 1948	150.00
	*222-Gynecological Endocrinology	24 sessions, part time, beginning Jan. 4, 1949	150.00
	*309-Diseases of the Thyroid and Other Endocrine Glands and Disorders of Nutrition	Fridays, part time, Jan. 7-Feb. 25, 1949	45.00
Association for the Study of Internal Secretions, 1200 N. Walker St., Oklahoma City 3, Okla. At: Los Angeles, Calif.	Endocrinology	Not given	Not given
American College of Physicians, 4200 Pine St., Philadelphia 4 At: Thorne Hall, Northwestern University, Chicago	Endocrinology	1 week, Nov. 8-13, 1948	30.00[21] 60.00[22]

ENDOSCOPY

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago 12	Practical Cystoscopy	10 days, part time, every two weeks	150.00
Harvard Medical School, Courses for Graduates, 25 Shattuck St., Boston 15 At: Massachusetts General Hospital	Endoscopy	2 months, arranged	250.00[24]

Graduate School of Medicine, University of Pennsylvania, 237 Medical Laboratories, Philadelphia 4	Orthopedics	8 months, October 1948-June 1949	800.00
	Orthopedics	12 months, October 1948-September 1949	1000.00
	OTOLARYNGOLOGY		
Graduate School of Medicine, University of Florida, 2033 Riverside Ave., Jacksonville At: Miami Beach, Florida	Midwinter Seminar in Otolaryngology and Ophthalmology	6 days, full time, January 10-15, 1949	Not giver
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago 12	Two Weeks Course in Otolaryngology[1]	2 weeks, full time, October 1948	200.00
Northwestern University Medical School, 303 E. Chicago Ave., Chicago 11	Audiology and End-Aural Otologic Surgery	1 month, full time, October 1948	500.00
	Basic Otolaryngology	9 months, full time, October 1948	800.00
	Fenestration Surgery[56]	2 months, full time, November 1948	500.00
Tulane University of Louisiana Division of Graduate Medicine, 1430 Tulane Ave., New Orleans 13	Otolaryngology	10 months, July 1, 1948-April 30, 1949	500.00
Harvard Medical School, Courses for Graduates, 25 Shattuck St., Boston 15 At: Harvard Medical School and Massachusetts Eye and Ear Infirmary	Otolaryngology - Basic Sciences	8 months, full time, Oct. 1, 1948-May 31, 1949	900.00
American Academy of Ophthalmology and Otolaryngology, 100 First Ave. Bldg., Rochester, Minnesota	Ophthalmology and Otolaryngology (Home Study Courses)	September 1948 to May 1949	10.00
At: The Palmer House, Chicago	Annual Meeting of the Academy (Lectures on Various Subjects in Ophthalmology and Otolaryngology)	October 10-15, 1948	1.50[51]
Columbia University College of Physicians and Surgeons, 630 W. 168th St., New York 32 At: Columbia-Presbyterian Medical Center At: Mount Sinai Hospital	Otolaryngology PM 1 - Bronchoscopy[1]	3 weeks, part time, Oct. 11-29, 1948	250.00
	Otolaryngology PM 30 - Histopathology of the Ear[1]	6 weeks, part time, Oct. 19-Nov. 26, 1948	50.00
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St., New York 29	Division of Graduate Studies, Basic Medical Sciences-Surgery, Medicine, Obstetrics and Gynecology, Pediatrics, Radiology, Urology, Otolaryngology, Pathology, Anesthesiology	9 months, October 1948	600.00
New York Polyclinic Medical School and Hospital, 345 W. 50th St., New York 19	Clinical Otolaryngology	6 weeks, part time, October 1, 1948	75.00
	Clinical Otolaryngology	3 months, part time, October 1, 1948	100.00
	Clinical Otolaryngology	6 weeks, part time, January 2, 1949	75.00
	Clinical Otolaryngology	3 months, part time, January 2, 1949	100.00
	Clinical Otolaryngology and Ophthalmology	6 weeks, full time, October 1, 1948	100.00
	Clinical Otolaryngology and Ophthalmology	3 months, full time, October 1, 1948	150.00
	Clinical Otolaryngology and Ophthalmology	6 weeks, full time, January 2, 1949	100.00
	Clinical Otolaryngology and Ophthalmology	3 months, full time, January 2, 1949	150.00
	Ophthalmology and Otolaryngology Including Cadaver Courses and Refraction	3 months, full time, October 1, 1948	600.00
	Ophthalmology and Otolaryngology Including Cadaver Courses and Refraction	3 months, full time, January 2, 1949	600.00
	Otolaryngology and Ophthalmology	9 months, full time, October 1, 1948	1000.00

Postgraduate Courses for Practicing Physicians—Jyly 1, 1948 to January 15, 1949—Continued

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
	OTOLARYNGOLOGY—Continued		
New York Post-Graduate Medical School, 303 E. 20th St., New York 3	#600 - Diagnostic Procedures in Otolaryngology	Sections A, B and C, (12 sessions each, part time) by arrangement	40.00[58]
	#620 - Symposium on Otolaryngology	10 days, full time, November 8-20, 1948	150.00
Graduate School of Medicine, University of Pennsylvania, 237 Medical Laboratories, Philadelphia 4	Otolaryngology	8 months, October 1948-June 1949	800.00
Virginia Society of Ophthalmology and Otolaryngology, University Station, Charlottesville At: University of Virginia Hospital	Post-Graduate Course in Ophthalmology and Otolaryngology	4 days, Nov. 3 and Dec. 1, 1948[52] Dec. 2-3, 1948[53]	25.00[54] 15.00[55]
	OTORHINOLARYNGOLOGY		
Georgetown University School of Medicine, 3900 Reservoir Road, N.W., Washington, D.C. At: Georgetown Medical Center	Intensive Graduate Course-Otorhinolaryngology	2 weeks, dates indefinite	150.00
State University of Iowa College of Medicine, University Campus, Iowa City	Otolaryngology-Rhinology-Otology	5 days, full time, Nov. 29, 30-Dec. 1, 2 and 3, 1948	50.00
New York Polyclinic Medical School and Hospital, 345 W. 50th St., New York 19	Eye, Ear, Nose and Throat, including Cadaver Courses and Refraction	3 months, full time, October 1948	600.00
	PATHOLOGY		
University Extension, University of California Medical School, Los Angeles 24, in cooperation with University Medical Extension, University of California, San Francisco 22 At: University Extension, Los Angeles	Surgical Pathology	12 weeks, part time, Sept. 22-Dec. 8, 1948	50.00
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago 12	Gross Pathology	1 month, full time, every month	150.00
	Gross Pathology	12 months, full time, by appointment	500.00
	Gross and Microscopic Pathology	Hourly basis, by appointment	To be arranged
	Pathology and Laboratory Medicine	10 weeks, part time, October 1948	100.00
	One Month Course - Surgical Pathology	4 weeks, full time, every month	250.00
	Surgical Pathology One Day Each Week	10 weeks, part time, October 1948	100.00
	Two Weeks Course in Surgical Pathology	2 weeks, full time, every two weeks	150.00
Michael Reese Hospital Postgraduate School, 29th St. and Ellis Ave., Chicago 16	Pathologic Diagnosis	10 weeks, part time, Oct. 13-Dec. 15, 1948	50.00
Wayne University College of Medicine, 1516 St. Antoine St., Detroit, Mich.	Neuropathology	12 weeks, part time, Dec. 13, 1948-Mar. 19, 1949	50.00
	Pathology of Bone and Joint Diseases	12 weeks, Dec. 13, 1948-March 19, 1949	50.00
	Pathology of Heart and Blood Vessels	12 weeks, Sept. 20-Dec. 11, 1948	50.00
	Pathology of Parasitic Diseases	12 weeks, Dec. 13, 1948-March 19, 1949	50.00
	Surgical Pathology	12 weeks, part time, Sept. 20-Dec. 11, 1948	50.00
	Urologic Pathology	12 weeks, Sept. 20-Dec. 11, 1948	50.00
At: City of Detroit Receiving Hospital	Medical Pathologic Conference	12 weeks, part time every quarter	15.00
	Pathology Review	12 weeks, part time, Sept. 20-Dec. 11, 1948	15.00
	Pathology Review	12 weeks, part time, Dec. 13, 1948-Mar. 19, 1949	15.00
At: Wayne County General Hospital, Eloise	Medical Pathologic Conference	12 weeks, part time, every quarter	15.00
	Pathology Review	12 weeks, part time, Sept. 20-Dec. 11, 1948	15.00
	Pathology Review	12 weeks, part time, Dec. 13, 1948-Mar. 19, 1949	15.00
Columbia University College of Physicians and Surgeons, 630 W. 168th St., New York 32 At: Mount Sinai Hospital	Pathology PM 30 - General and Special Pathology	3½ months, part time, Oct. 2, 1948-Jan. 22, 1949	60.00
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St., New York 29	Clinical Pathology	26 hours, arranged	100.00
	Division of Graduate Studies, Basic Medical Sciences-Surgery, Medicine, Obstetrics and Gynecology, Pediatrics, Radiology, Urology, Otolaryngology, Pathology, Anesthesiology	9 months, October 1948	600.00
	Pathology	16 weeks, half time, arranged	200.00

FOOTNOTES

1. Specialists
2. M.D.'s with special qualifications.
3. Priority given to residents in surgery.
4. Tution.
5. Registration fee.
6. Incidental fee.
7. For 12 weeks.
8. For 16 weeks.
9. For 8 weeks.
10. Per month.
11. A third week, $65.00
12. Books.
13. Instruments.
14. Anatomy 120 hours, Pathology 60 hours, Physiology 60 hours: Students may enroll for any one section.
15. Requirements: M.D. degree from approved medical school. Appointment in an assistant residency or preceptorship approved by American Board of Obstetrics and Gynecology. Personal Interview. Course has been approved by the Post-Graduate Survey Committee of the American Board of Obstetrics and Gynecology and may be presented for 6 months' credit towards certification by the Board.
16. $800.00 for surgery; $600.00 for other specialities.
17. Per week.
18. This course is specifically for Residents in this area.
19. Per semester.
20. Each city.
21. American College of Physicians (A.C.P.) members.
22. Non-members.
23. This course is planned for those who have taken Electrocardiography I or who have sufficient experience in the interpretation of electrocardiograms.
24. This course may be taken for more than 2 months, if the student wishes, and the tuition is $125.00 for each additional month.
25. Per quarter.
26. Weekly, for shorter courses.
27. Internal Medicine, may be arranged in special cases, provided places are available, for 3 months beginning October 4, 1948, January 3, 1949 or April 4, 1949. ($250.00 for 3 months).
28. Trainee is paid $10.00 per day while on duty. It is required that at least 50% of the trainee's time be taken up with the diagnosis and treatment of cancer and that he will be on duty full time as an integral member of the hospital staff.
29. Intern and Resident.
30. Ten lectures.
31. Single lecture.
32. Per day.
33. Charge for non-members.
34. No charge for members.
35. For complete series.
36. Registration is gratis to men of armed services, residents and interns of hospitals and senior and junior medical students of the University of Kansas.
37. Eligibility limited to physicians practicing in Rochester Region.
38. Per course.
39. Complete course.
40. Per year.
41. For advanced students in training.
42. $300.00 the first year; $100.00 the following years
43. Approved psychiatric training required to qualify for the course.
44. For those with some training in psychoanalysis.
45. Primarily for students in analysis.
46. Special course open to staff and members of mental institutions.
47. Full course.
48. Lecture course only.
49. Course is limited to applicants whose biographical data is approved by a special committee.
50. Possibly $700.00.
51. Per hour.
52. Otolaryngology.
53. Ophthalmology.
54. 4 days.
55. 2 days.
56. Open only to selected members of course in Audiology and End-Aural Otologic Surgery.
57. Per two-month periods.
58. Each section - per 12 sessions.
59. Proctology I is prerequisite to Proctology III.
60. Course may be taken 6 days a week for one month or 3 days a week for 2 months.
61. Course devised specifically for physicians practicing in New York State as preparation for position of local health officer.
62. Limited to physicians who have a working knowledge of Radiology.
63. 31 weeks, full time, for veterans: 6 months or longer for others.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in THE JOURNAL, June 12, page 661

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Juneau, Last week in Aug. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau. Examination

FLORIDA: Examination. Gainesville, Nov. 6. Final date for filing application is Nov. 6., Mr. M. W. Emmel, University of Florida, Gainesville.

IOWA: Des Moines, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Hapids.

MICHIGAN: Examination. Ann Arbor and Detroit, Oct. 8-9. Sec., Miss Eloise LeBeau, 1510 West Allegan St., Lansing.

NEBRASKA: Examination. Omaha, Oct. 5-6. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, Room 1009 State Capitol Bldg., Lincoln.

NEW MEXICO: Examination. Santa Fe, June 27. Sec., Miss Marguerite Kilkenny, State Capitol Bldg., Santa Fe.

OKLAHOMA: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: Examination. Portland, Sept. 4. Sec., Basic Science Examining Committee, Dr. C. D. Byrne, Univ. of Oregon, Eugene.

TENNESSEE: Examination. Memphis, July 5-6. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis.

WASHINGTON: Examination. Seattle, July 7-8. Act. Dir., Dept. of Licenses, Mr. G. C. Starlund, Sec., Miss Virginia Wotherspoon, Olympia.

WISCONSIN: Examination. Madison, Sept. 25. Final date for filing application is Sept. 18. Sec., Prof. W. H. Barber, Scott & Watson Sts., Ripon.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

American Journal of Physiology, Baltimore
151:239-652 (Dec.) 1947. Partial Index

Relation of Salivary Flow to Thirst Produced in Man by Intravenous Injection of Hypertonic Salt Solution. J. H. Holmes and M. I. Gregersen. -p. 252.

Displacement of Blood from Lungs by Pressure Breathing. W. O. Fenn, A. B. Otis, H. Rahn and others. -p. 258.

Oxygen and Carbon Dioxide Tensions of Alveolar Air and Arterial Blood in Healthy Young Adults at Rest and After Exercise. M. Galdston and A. C. Wollack. -p. 276.

Measurement of Plasma Volume as Distribution Volume of Injected Autogenous Plasma. H. C. Lawson, O. W. Shadle, J. C. Moore and D. T. Overbey. -p. 297.

Peripheral Visual Acuity of 55 Subjects Under Conditions of Flash Presentations. F. N. Low. -p. 319.

Plasma Ac-Globulin Activity. R. C. Murphy, A. G. Ware and W. H. Seegers. -p. 338.

Protection of Cerebral Circulation by Cerebrospinal Fluid Under Influence of Radial Acceleration. R. F. Rushmer, E. L. Beckman and D. Lee. -p. 355.

Effect of Dilute Saline Solutions on Gastric Potential and Secretion of HCL. L.E. Hokin and W.S. Rehm. -p. 380.

Role of Dietary Protein in Experimental Liver Regeneration: Nitrogen Balance Study. H. M. Vars and F.N. Gurd. -p. 391.

*Working Capacity in Patients with Orthopedic Handicaps from Poliomyelitis. I. Energy Expenditure in Walking at Various Speeds and Grades. E. Simonson and A. Keys. -p. 405.

Forces Exerted at Different Velocities in Human Arm Movements. R. J. Dern, J. M. Levene and H. A. Blair. -p. 415.

Blood Volumes of Normal Children. Minerva Morse, D. E. Cassels and F. W. Schultz. -p. 438.

Roentgenographic Study of Effect of Pneumatic Anti-Blackout Suit on Hydrostatic Columns in Man Exposed to Positive Radial Acceleration. R. F. Rushmer. -p. 459.

Effects on Man of High Concentration of Carbon Dioxide in Relation to Various Oxygen Pressures During Exposures as Long as 72 Hours. W. V. Consolazio, M. B. Fisher, N. Pace and others. -p. 479.

Transient Hypotension Following Rapid Intravenous Injections of Hypertonic Solutions. E. E. Muirhead, R.W. Lackey, C. A. Bunde and J. M. Hill. -p. 516.

Increased Tolerance to Severe Anoxia on Carbon Dioxide Administration. R. F. Kline. -p. 538.

Types of Afferent Fibers in Phrenic Nerve. R. M. Kohrman, J. B. Nolasco and C. J. Wiggers. -p. 547.

Influence of High Fat Diets on Alloxan Diabetes. R. G. Janes and M. Prosser. -p. 581.

*Variations in Effect of Anoxia on Performance. D. M. Green. -p. 588.

*Observations on Effects of Adrenalin on Renal Function and Circulation in Man. J. A. Barclay, W. T. Cooke and R. A. Kenney. -p. 621.

Thermal Exchange of Man at High Temperatures. N. Nelson, L. W. Eichna, S. M. Horvath and others. -p. 626.

Working Capacity in Orthopedic Handicaps from Poliomyelitis.—Simonson and Keys compare energy expenditures of 2 poliomylitis patients, 1 clinically completely recovered from paralysis (E. B.), the other with an almost atrophic right leg (J.D.), to those of 2 normal subjects during walking on a treadmill at different speeds and grades. E.B.'s energy expenditure coincided with the normal values at all variations of speed up to 3.5 miles per hour with a slight tendency to higher values at 4 miles per hour. J.D.'s energy expenditure when walking with braces exceeded the normal values (1.5 to 2.6 times) at all variations investigated (up to 3 miles per hour). Without braces, J.D.'s energy expenditure was considerably higher than it was with braces. The respiratory efficiency of J.D. was definitely lower than that of the other subjects, at all variations. The level of the energy expenditure at a given variation characterizes the degree of handicap of a given patient. The trend of the curves indicates that 4 miles per hour is the limit of tolerance for E.B., and 2.5 miles per hour for J.D. The level of energy expenditure appears to be a good index for the relief obtained by means of braces. It is possible that this method could be used to compare different types of braces. The ability to maintain a steady state of oxygen consumption appears to be a good index for fatigue trends. The comparatively low oxygen debts of both J.D. and E.B. indicate that the breakdown of the steady state is not due to cardiovascular insufficiency. The maximum level at which the steady state can be maintained in normal subjects depends on the cardiovascular capacity for oxygen transport. Patients with orthopedic handicaps are obviously not able to reach this limit. Therefore, the increase of the oxygen consumption with continuation of walking is obviously due to the increasing use of auxiliary muscle groups. This might explain why in E.B. the breakdown of the steady state was not associated with an increased oxygen debt. The drop of the respiratory efficiency appears to be a good criterion for the limit of working capacity and for fatigue of patients with orthopedic handicaps as well as of normal subjects.

Effect of Anoxia on Performance.—According to Green, variations in the effect of anoxia on human performance may significantly alter the relative efficiency of persons working under lowered oxygen tensions. Among the factors known to influence these variations are rate of ascent, degree of activity and duration of exposure, state of health, psychogenic disorders and cardiovascular disease. However, when these factors are equalized, a considerable range of variation still remains. This study was undertaken to determine the relationship of anoxic alterations in individual neuromuscular functions to one another and to the mean performance of the subject. The differences in percentage impairment of various aspects of group performance indicate that the quantitative changes observed under conditions of anoxia depend not only on the subject but on the nature of the function under study. Net performance under such conditions is a composite result of alterations in a number of functions not similarly affected by an identical change in oxygen pressure. Individual subjects under anoxic conditions exhibit a considerable degree of variation both as to net decrement in performance and as to relative impairment of particular functions. As a consequence, tests which measure a single function are not apt to be of selective value in singling out the persons who can perform with maximum over-all effectiveness under low oxygen tensions.

Effects of "Adrenalin" on Renal Function.—Barclay and his co-workers point out that during exercise there is diminution in renal plasma flow and glomerular filtration rate, and in an attempt to elucidate the possible role of epinephrine ("adrenalin") in producing such changes the effects of the administration of the hormone on the renal hemodynamics in man have been reinvestigated. The subjects were students with normal renal function. Eight hundred milliliters of water were given by routh to insure adequate flow of urine. Renal plasma flow and glomerular filtration rate were determined. After two or more control periods, epinephrine was administered to 6 subjects intramuscularly and to 8 subjects by a continuous intravenous infusion. Blood pressure was determined by auscultation, and pulse rates were taken at intervals. A fall in inhibition of urinary flow was inconstant. There was no evidence that epinephrine plays a significant part in the renal picture seen in exercise.

Hemoconcentration After Electric Convulsions.—In view of the fact that variations in the water balance influence the activity of the cerebral cortex and cause important changes in the body as a whole, Altschule and his co-workers decided to investigate the occurrence of hemoconcentration during the violent muscular contractions of electrically induced convulsions. Fifty-five studies of hematocrit readings and sixty determinations of plasma protein were made before and after routine electroshock treatments on 10 patients. It was found that hemoconcentration and decreased plasma volume occur regularly. Curare diminishes but does not abolish these changes. It is suggested that the decreases in plasma volume are probably important in explaining the fall in venous and arterial pressures noted toward the end of electrically induced seizures in many patients. The question arises whether the brief periods of muscular contraction occurring during electrically induced convulsions can cause the same type of response of the pituitary gland as a more protracted voluntary muscular effort. In the studies based on protracted exercise, antidiuretic hormone was liberated in detectable amounts only during a brief initial period of the exertion. The data of the present study are no more than suggestive in regard to activation of the function of the posterior lobe of the pituitary as a consequence of changes in the blood during electrically induced convulsions. Definite conclusions must await an attempt to evaluate the role of the passage through the brain of the electric current itself, with direct stimulation of the hypothalamic-hypophysial mechanisms.

*Unilateral Syphilitic Primary Atrophy of Optic Nerves. Anatomic Study of 2 Cases. W. L. Bruetsch. -p. 80.

Syphilitic Atrophy of Optic Nerve.—Bruetsch says that in his anatomic material of 12 cases of syphilitic primary optic nerve atrophy, death had occurred in 2 at a time when the atrophy was confined to one optic nerve. Microscopic studies on the visual pathways in these 2 cases are presented. They furnished the clue to the ultimate degeneration of the nerve fibers of both optic nerves. The author arrives at the conclusion that unilateral syphilitic primary atrophy of the optic nerve is almost always the forerunner of bilateral atrophy of this nerve. At the time the demyelination of the nerve fibers has progressed to complete degeneration in one optic nerve, there is already present in the normal nerve a syphilitic inflammatory exudate which ultimately will lead to atrophy of the not yet demyelinated optic nerve. Syphilitic optochiasmatic arachnoiditis, which is frequently present in neurosyphilis, has nothing to do with the causation of the atrophy of the optic nerves. The most efficacious treatment of syphilitic atrophy of the optic nerve is malarial therapy, aided by concomitant and subsequent courses of penicillin, each course consisting of administration of at least 5,000,000 units.

Granuloma Inguinale.—Frost and Ryan say that the increase in the Negro population in California has been accompanied by a greater incidence of granuloma inguinale. Since most medical texts stress the inguinal manifestations rather than the earlier genital lesions, many cases are at first not recognized or have been confused with other venereal diseases. Granuloma inguinale usually begins with a vesicle, papule or nodule on the preputial orifice, the labia minora or the vaginal wall. Of 8 cases of granuloma inguinale seen at Oakland City Clinic in a period of six months, all but 1 presented lesions confined to the genitalia. The chronicity of the lesions on the external genitalia is of differential diagnostic value. The diagnosis depends on the demonstration of the pathognomonic Donovan bodies in spreads which are prepared by crushing curetted material from the lesions between glass slides. The Donovan body, which *can be stained with Wright or Giemsa stains,* may be found extracellularly or within the cytoplasm of the large monocytes. These bodies look like a closed safety pin due to their elongated ovoid shape and intense bipolar staining reaction. The disease usually responds favorably to antimony compounds. Stibophen is considered to be the drug of choice.

Treatment of Idiopathic Ulcerative Colitis.—Machella and Miller recommended ileostomy to a young woman with chronic idiopathic ulcerative colitis, who was not responding to the usual medical measures. When she refused, it was decided to try to simulate a surgical ileostomy. The procedure consisted of introducing a Miller-Abbott tube into the terminal ileum and of maintaining constant suction so as to prevent the intestinal contents from reaching the diseased colon. To assure an adequate amount of protein food and to lessen the chances of the tube's becoming obstructed by solid matter, the oral administration of a solution containing equal parts of an enzymatic casein digest and of "dextri-maltose" was selected. The result in this patient was so satisfactory that it has been used in the treatment of others. The tube was kept in place for a period of seven to fifteen days. It was withdrawn when the volume of fluid aspirated had decreased sufficiently to indicate that most of the ingested solution was being absorbed and the patient was improving clinically. After the tube was withdrawn, the administration of the hydrolysate-"dextri-maltose" solution was continued until sigmoidoscopy revealed evidences of healing. At that time low residue foods were gradually added. Following discharge, the patient was advised to adhere strictly to the low residue diet. The 14 cases of idiopathic ulcerative colitis treated in this manner represent 12 patients, 2 of whom had relapses. A remission was induced in 11 of 12 patients, 9 of whom are still in remission after periods varying from two to twelve months. A relapse has occurred in 2 patients, in one after 7, and in another after 9 months of freedom from symptoms. A remission has again been induced in each of the 2. The 11 improved patients are in useful activity or gainful employment.

Hepatic Dysfunction in Ulcerative Colitis.—The study reported by Ross and Swarts was motivated by their observations of a patient whose ulcerative colitis was apparently complicated by severe hepatic disease and who ultimately died in hepatic failure. Twenty cases of chronic ulcerative colitis have been studied with the aid of liver function tests to determine evidence of active or latent hepatic damage. Two cases involving damage to the liver are discussed in detail. One hundred and fifty unselected cases of chronic ulcerative colitis were reviewed to determine the proportion of cases showing gross clinical evidence of hepatic disease. None was found. Twenty-seven cases of chronic ulcerative colitis were analyzed at necropsy for hepatic disease and were compared with 100 unselected necropsied cases in which death occurred from other causes. There was no greater incidence of hepatic insufficiency than occurs in other diseases in which uncorrected factors of severe anemia, weight loss and/or negative nitrogen balance appear. Sepsis or other hepatoxins or both add to the degree of hepatic damage. An analysis of the 20 specially studied clinical cases did not alter the pattern of incidence of damage to the liver. There is a trend toward hepatic insufficiency when weight loss, anemia and activity of the ulcerative disease are severe. The most significant results of liver function tests portending this change in hepatic function are a low serum protein level and/or the tendency to, or reversal of, the albumin-globulin ratio. The authors believe that correction of such factors as malnutrition and coincident protein deficit, plus correction of anemia when it is severe, are not only necessary measures in the treatment of chronic ulcerative colitis but offer needed protection to the liver.

Gastroscopic Observations in Pernicious Anemia. Hardt and his co-workers made gastroscopic studies on 100 patients with pernicious anemia. Nearly half of the patients were subjected to gastroscopy on two or more occasions. Atrophy was found in 59 of the patients; that is, *it is not present in all* cases of pernicious anemia. Atrophy of the gastric mucosa was not related to the length of time the disease was present, the amount of previous liver therapy or the existing blood picture. Only 9 of 47 patients showed improvement in the appearance of the mucosa while under liver therapy, while 4 previously normal mucosas showed atrophy on reexamination. Polyps were found in 7 patients and carcinoma in 1 patient; the latter developed while the patient was under liver therapy. Repeated roentgen ray and gastroscopic studies are *indicated* in every pernicious anemia patient to discover as early as possible the presence of gastric carcinoma.

Ion Transfer of Penicillin.--The experiments described by Pereyra were carried out to clarify the problem of ionic transfer of penicillin. It was found that without iontophoresis penicillin applied to the intact skin does not enter the body in amounts sufficient to be detected in the urine, but that sodium and calcium penicillin in adequate concentration in aqueous solution are effective electrolytic salts, and that penicillin applied to the intact skin by iontophoresis is absorbed into the body and is excreted in the urine in appreciable amounts. Only the negative electrode of the galvanic current applied to solutions of these salts effects the transfer of penicillin into the body. The transfer is accomplished most readily from free aqueous solutions of the salts, less readily from gauze pad applicators saturated with penicillin solution. The base was cut from an Erlenmeyer flask, and this open base was sealed to the skin with collodion applied to the rim. Eighty milliliters of penicillin solution were then poured into the glass chamber and the top closed with a stopper supporting a helical coil of copper wire which extended into the solution. This wire was connected to the negative terminal of a galvanotherapy unit. The positive terminal was connected to a thick layer of gauze wet with isotonic sodium chloride solution and wrapped around one leg. The application of penicillin by iontophoresis to the skin does not produce bacteriostatic blood levels of penicillin; the amount of penicillin recoverable in the urine following penicillin iontophoresis to the skin varies directly with the concentration of the solution, the duration of treatment and the strength of the current employed. Penicillin applied by iontophoresis is effective in the treatment of chancroidal ulcers.

Cotton Knots.--Byron says that it is usually stated that when cotton is used no attempt need be made to obtain a true square knot by crossing hands, and the suture may be cut "on the knot." In one of the operating rooms of a Marine field hospital during the Okinawa campaign, cotton was used as suture material. It was noted at the operating table that all too frequently the three knot tie had a disconcerting way of untying when a sudden strain was placed on the suture. Subsequently experiments with cotton suture material were made on a thread tester. It was found that the tensile strength of cotton is roughly proportional to the size. Double thread is slightly more than twice as strong as single thread. The presence of a knot in a thread weakens it by 18 to 33 per cent. A satisfactory knot with cotton which will not untie should be three square knots made by crossing hands and cut 1½ mm. from the knot.

Streptomycin in Acute Brucellosis.--Page and his associates report the case of a veterinarian, aged 22, who had been engaged in the manual removal of placentas from cows with Brucella abortus infection. He stated that headaches, moderate fever and malaise had persisted five to six weeks and that for three weeks he had had daily shaking chills and generalized aching late in the afternoon with elevations of temperature to about 103 F. An aggulutination test was reported positive for brucellosis in a dilution of 1:6,400. About six days prior to admission the patient received an injection of Brucella antiserum intramuscularly without effect on his clinical condition. The patient lost an additional 15 pounds (6.8 Kg.) during his first twenty days in the hospital. From the twenty-first to the twenty-seventh day, there was a slow downward curve in the temperature peak, chills disappeared and the patient began to improve subjectively. Intramuscular streptomycin therapy was begun on the twenty-ninth hospital day and after Brucella abortus had been isolated from blood culture. Four days after the initiation of streptomycin therapy the temperature began to subside, reaching normal on the eleventh day of therapy. Five months later the patient had returned to work and had regained his normal weight without return of signs or symptoms of the disease. The authors say that they reported this case because the status of streptomycin therapy in the treatment of infections due to Br. abortus is unsettled. Keefer has recently stated that chronic infections with Brucella organisms have shown poor response to the use of streptomycin.

Book Notices

Gifford's Textbook of Ophthalmology. By Francis H. Adler, M.D., Professor of Ophthalmology, University of Pennsylvania Medical School, Philadelphia. Fourth edition. Cloth. Price, $6. Pp. 512, with 310 illustrations. W. B. Saunders Co., West Washington Square, Philadelphia 5. 1947.

The fourth edition of this textbook, which has been revised by Dr. Francis H. Adler, lays more stress on information of practical value that the undergraduate and practicing general physician should know. Consequently, the technics of refraction and operations have been considerably condensed. The various surgical procedures are given in a separate chapter, so that the reader may refer to them when necessary without interrupting the subject under discussion. There is a completely new chapter on Ocular Disorders due to diseases of the central nervous system, which was not included in the previous edition. The chapter on Disturbances of Ocular Motility has been rewritten to coincide with the new author's point of view from the physiologic standpoint. The chapter on Ocular Manifestations of General Diseases has been considerably enlarged and includes the newer methods of treatment such as the use of penicillin and streptomycin. There are about one hundred more illustrations, which greatly enhance the reading value. The discussions are practical and concise, the illustrations are carefully designed to supplement the text and the contents are succinct and well organized. The book is to be recommended to the medical student and general practitioner as well as to the ophthalmologist.

Epilepsy; Psychiatric Aspects of Convulsive Disorders. Edited by Paul H. Hoch, M.D., New York State Psychiatric Institute, New York, and Robert P. Knight, M.D., the Menninger Clinic, Topeka, Kan. The Proceedings of the Thirty-Sixth Annual Meeting of the American Psychopathological Association, Held in New York, May 1946. Cloth. Price, $4. Pp. 214, with illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1947.

This slender volume contains the fifteen papers read at the meeting of the American Psychopathological Association in May 1946. The contributions are strangely diverse—the new and the old, the physical and the psychical. In the former group are excellent up-to-date discussions of drug therapy (Merritt), of electroencephalography (Jasper) and of heredity (Kallmann and Sander). There is presentation of data on the prevalence of epilepsy (Malzberg), its social implications (Collier), mental testing (Mayman and Rapaport) and the behavior and educational problems of patients of the Baird Foundation Clinic. Convulsions in animals were induced by application of certain substances to the cortex (Kopeloff and Pacella) and by auditory stimuli (Patton). Problems of the psychology and personality of epileptic persons are discussed in four papers by Foxe, Piotrowski, Diethelm and Mittelmann, respectively. These serve to emphasize the failure of psychiatrists and psychologists to show that peculiar personality is a cause or an essential feature of epilepsy. The authors point out the need for the collection and study of data in this important but difficult field. The book illustrates the extent to which psychologic research has failed to keep pace with medical research in the field of epilepsy.

Prognose und Erblichkeitsmomente bei Ekzema infantum: Eine klinisch-statistische Untersuchung von Allergieerscheinungen. Von Gunnar Edgren. Inauguraldissertation welche mit gehöriger Genehmigung der weiterfahrenen medizinischen Fakultät zu Uppsala. Paper. Pp. 204. Appelbergs Boktryckeriaktiebolag Uppsala, 1943.

The monograph reports a follow-up study of 381 cases of infantile eczema compared with 454 noneczematous controls. Special attention is given to heredity and nutrition in the causation of the disease and to its prognosis with respect to allergic manifestations such as seasonal rhinitis, bronchial asthma, urticaria, papular urticaria (strophulus) and angioneurotic edema. All patients had been seen in pediatric wards or clinics during the first two years of life; the interval between first and last observation varied from a minimum of seventeen years to a maximum of thirty-eight years. Allergic diseases were commoner in parents and siblings of eczematous children than in those of controls, but the presence of environmental factors prevented definite conclusions about the mechanism of inheritance. Infantile eczema occurred more frequently in boys than in girls. The average age of onset was 5 months. The initial lesion healed at an average age of 2 years, but one fourth of the cases cleared up at as early as 15 months, one quarter at as late as 3⅓ years. Besnier's prurigo followed in 18 per cent of the cases; eczema recurred in 24 per cent, but never more than once in the same patient. No difference was found in the incidence of infantile eczema in breastfed and bottlefed children. Forty-two per cent of the eczematous children had occasional allergic symptoms (controls, 10 per cent); 21 per cent were continuously affected (controls, 2 per cent), and only 37 per cent remained free of symptoms: these figures seemed to support the existence of a common hereditary factor in infantile eczema and other allergic manifestations. Patients whose parents had allergies and those with early and extensive eczema showed a high incidence of allergic symptoms in later years; bronchial asthma is more apt to develop in boys with infantile eczema than in girls. The mortality rate of the eczematous group does not differ from that of the noneczematous controls.

Calcific Disease of the Aortic Valve. By Howard T. Karsner, M.D. and Simon Koletsky, M.D. Fabrikoid, Price, $5. Pp. 111, with 24 illustrations. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1947.

In this monograph the authors present a new and authoritative evaluation of an old and controversial subject. Beginning with Valsalva, they have made a comprehensive survey of the literature on calcific disease of the aortic valve. They have reviewed the classic studies of Monckeberg on the histology of normal and sclerotic aortic valves, and with this as a background they have analyzed their own 200 cases observed at necropsy. The anatomic analysis is carefully made, and with the aid of proper statistics they have been able to extract from their material a truer picture of certain factors involved in this disease than have any previous investigators. Excellent tables, charts and photographs help to present clearly the typical anatomic observations and the numerical data.

The authors point out the preponderance of cases in persons over 50 years of age, the relatively high incidence in males as opposed to females (1.6 to 1 when the corrections are made for the relative proportions of males to females in the autopsy population) and the low incidence in the Negro race. Cardiac enlargement, although a prominent factor in many cases, was not present to a significant degree in a large percentage. Rheumatic stigmas in various forms and of varying degrees were definitely demonstrable in 196 of 200 hearts examined. Microscopic evidence of rheumatic disease was usually present in more than one valve, but deforming valvular disease of a single valve was present in slightly less than half of the cases. The authors conclude from their studies that in all but a rare instance calcific disease of the aortic valve is the result of rheumatic cardiac disease.

Clinical features of the cases are described in detail. The diagnosis of aortic stenosis was offered in only 48 of 190 cases in which it might possibly have been made in life. Cardiac enlargement, systolic aortic murmurs and thrills, and left ventricular preponderance in the electrocardiogram appear to be *the most dependable clinical signs.* It is pointed out that roentgenologic studies have more to offer to clinical diagnosis than any other single method of observation. This book is highly recommended for those interested in diseases of the heart.

The Clinical Examination of the Nervous System. By G. H. Monrad-Krohn, M.D., F.R.C.P., Professor of Medicine in the Royal Frederick University, Oslo. Eighth edition. Fabrikoid. Price, $4.50. Pp. 380, with 126 illustrations. Paul B. Hoeber, Inc., 49 E. 33d St., New York 16, 1947.

The present edition of this excellent book on the clinical examination of the nervous system is larger and is entirely up-to-date. It has been thoroughly revised and recast. The author is one of the great neurologists of the world, and his book is essentially based on the fact that the physician must examine his patient in order to determine the nature and location of the disease or lesion. Angiography is discussed and in the opinion of the author is a great stride forward in intracranial diagnosis. This book is one of the best on clinical examination in neurology. It is highly recommended for all medical students, residents and general practitioners.

Practical Office Gynecology. By Karl John Karnaky, M.D., Assistant Professor of Clinical Gynecology, Baylor University College of Medicine, Houston, Texas. Fabrikoid. Price, $7.50. Pp. 261, with 113 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1947.

The information presented in this book is based on laboratory and clinical investigations of Trichomonas vaginalis, Monilia albicans and leukorrhea. These subjects therefore are emphasized in the book, but of course others are included, particularly endocrinology, sterility, disorders and infections of the external and internal genitals and orthopedic and urologic aspects of gynecology. These chapters are proper subjects for a treatise on practical office gynecology, as is also the interesting chapter on "Some Psychological Aspects of Gynecology" written in collaboration with Louis Spivak. However, it is difficult to see why the author included in a book on office gynecology the following chapters: "Pregnancy Tests, Management of Abortion, Premature Labor and Postpartum Bleeding" and "Ovarian Pathology," which includes more than three pages of illustrations of ovarian tumors and a discussion of surgery of the ovary. Other illustrations which have nothing to do with office practice are those of intestines removed during a criminal abortion, surgical specimens of utero-ovary, Brenner and granulosa cell tumors, hydatid mole and other neoplasms.

The author is fond of injecting estrogens into the anterior wall of the cervix to control bleeding, and he says he injects as much as 25 cm. of an oily vehicle into the cervical muscle (p. 39). In the treatment of infantile uterus the author states that "a properly fitted flexible stem pessary which induces strong contractions with concomitant myometrial development may be helpful (Bickers)." This is a dangerous recommendation for general practitioners, and the author himself must have realized this because he added a footnote saying the "Uterector, a soft flexible stem pessary, should be employed only by those experienced in its use since it can produce more harmful than beneficial effects under some circumstances. It is a dangerous instrument in the hands of the untrained physician." Then why even mention it in this book intended for general practitioners?

There is a full page colored illustration of the technic of uterotubal insufflation (p.55) using air as the gas. It is not safe to recommend the use of air for the determination of tubal patency, because harm can result from it. Carbon dioxide is the safest gas to use for this purpose. The book contains numerous beautiful and instructive black and white and colored illustrations, but unfortunately many of them have appeared in the advertisements of pharmaceutical manufacturers. In the opinion of the reviewer this fact detracts from the enjoyment of the book. Karnaky has written many articles on vaginal discharges, vaginal acidity and the use of estrogens. This is evident in the list of references, which occupies eleven pages. The author lists himself forty-three times for articles, discussions and correspondence to medical journals. The book is well printed on sturdy paper and the illustrations have been beautifully reproduced. It is hoped that in the next edition Karnaky will omit the data which have nothing to do with office practice and include a few other subjects which are of importance to general practitioners in their office practice.

Pédagogie du nourrisson et du premier âge. Par le Dr. A. Thooris. Paper. Price, 270 francs. Pp. 185. G. Doin & Cie, 8, Place de l'Odeon, Paris, 6^{e}, 1947.

An anthropologist ventures into child rearing on the basis of his personal experience with his own children. Dr. Thooris attempts to apply physiologic principles in the every day management of infants and children. He considers the newborn beneath the developmental level of an animal, since the lack of excitability of the hemispheres at birth makes the infant comparable to a decerebrate dog. This is the concept of the absolute infant reduced to several inherited reflexes but deprived of all means of satisfying them. The mother is in the directive position of transforming her absolute infant into a conditioned being. An acquired reflex cannot be stabilized unless it is reenforced by an absolute reflex. As a student of Pavlov the author classifies reflexes as subcortical and cortical. The former are hereditary, few in number, stable and nonfatigable by virtue of their rhythmic character. The latter comprise the reflex of life and death, the reflex of hunger, the reflex of inquiry, the reflex of freedom and the sexual reflex. Thooris considers the reflex of hunger basic for educational training throughout life. Unfortunately, he uses the methods of animal trainers to teach infants. Indeed, he addresses a plea to the mothers of France to nurse their babies with "live" milk from their breasts rather than with "dead milk" from the cow. He does not consider it a profanation to speak of this absolute infant at birth as equivalent to an absolute dog in spite of the horror this image conveys to the mother. The parallel is strengthened by the contention that the decerebrate dog and the newborn infant would each die in front of a bowl of food or a bottle full of milk if one did not put the morsel in the jaws of the animal or the nipple in the mouth of the baby. In the attempt to study the development of the child from the mechanistic concept, the author fails to view the offspring against his hereditary, social and economic background. It must be remembered that intrauterine life lays the foundation for the child's future life and that birth, though an unavoidable necessity, is but one milestone from the uterus to the grave. Compared with other animals the child is peculiar in that his instinctive habits are extremely complex. Thooris reveals with remarkable clarity how the child's reactions are formed only after long processes of development and conditioning. Behavior patterns such walking, which is spontaneous in animals, must be acquired by the child. He has to learn innumerable performances, which in later life become habitual, in a way acceptable to the social group of which he is a member. He is also expected to undergo scholastic education according to his ability to develop habit patterns of abstract and applied knowledge. The period of apprenticeship which he serves before reaching full intellectual and emotional development is associated with a corresponding period of gradually diminishing physical immaturity. The author rightly points out that the infant is exceptionally vulnerable not only to trauma but to extremes of temperature, changes in diet and exposure to infection. The central nervous system of the infant is poorly myelinized, his digestive function limited and his blood-forming organs readily disorganized. These are not the characteristics in the developmental course of young animals. Consequently, the methods of animal husbandry can only be orientations rather than applications for rearing infants. Even the methods advocated by Thooris are human compromises. The chapters on conditioning of infants and training of young children constitute a sensible system of child guidance in the cause of healthy maturity.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

INTERMITTENT CLAUDICATION

***To the Editor:*—What can be done to relieve intermittent claudication?**

M.D., Long Island, N. Y.

Answer.—Intermittent claudication is a symptom of the following conditions: severe sclerotic changes in the arteries of the legs; arteriosclerosis in the spinal cord in the lumbosacral region; thromboangiitis obliterans (Buerger's disease) and peripheral vascular spasm in the legs. This symptom is at times associated with gout, diabetes mellitus and syphilis. Those patients who have sclerotic changes in the arteries of the legs and spinal cord can at best be treated only symptomatically. Patients with thromboangiitis obliterans are supposed to have an increased viscosity of their blood as well as an increase in cholesterol content in their blood. If gout, diabetes or syphilis are present they should be adequately treated. If pain is present without walking (rest pain) then that patient should be put to bed for at least two months to improve the circulation in the legs and to reduce the viscosity of the blood by large copious amounts of liquids. Smoking should be absolutely forbidden. Vasodilators in the form of injections of sodium nitrite and methacholine chloride should be tried three to four times per week. Injections of tissue extract three times a week should also be tried. Phenobarbital and papaverine hydrochloride may be tried. If the patient's pain decreases or vanishes, then that patient must be told to walk only when necessary. He should not run or walk fast and should not participate in any exercise or sport requiring the use of his legs. Diathermy, periarterial sympathectomy and baths have been tried but have not proved valuable. Every effort must be made to prevent gangrene, because when it develops amputation of the involved extremity is indicated. All patients should be warned against injuries to the feet and wearing of tight shoes. They should not use hot water bottles and must be extremely careful in cutting corns and trimming nails.

TRANSPLANTATION OF OVARIES

***To the Editor:*—A patient states that she had both ovaries and tubes removed and that she menstruated over a year after the operation. She now desires to know whether it is possible to transplant viable ovaries and tubes from another person to her broad ligament and uterus. She would like to have a baby of her own.**

Is any surgeon capable of successfully performing such operations? My patient is willing to undergo operative intervention if there is a fairly reasonable chance of success.

Raymond M. Stover, M.D., Francesville, Ind.

Answer.—Neither the age of the patient nor the year of the operation is stated. If this patient had periodic bleeding for more than a year after her operation, she must have had some ovarian tissue left which functioned during this time.

There are many recorded cases of transplantation of a patient's own ovary or part of one from its normal location to a cornu of the uterus or within the uterine cavity. These are autoplastic operations. These operations are done for one or two reasons, namely to prevent menopausal symptoms and to permit pregnancy. Concerning the results of autoplastic operations, J. P. Greenhill (*Am. J. Obst. & Gynec.* **33:**39 [Jan.] 1937) says the following:

> *Von Graff collected 66 cases in which a graft of ovarian tissue was* placed on a uterine horn or on a tubal stump. He reported 14 pregnancies (21.2 per cent) following these operations. However, since only 5 of these pregnancies went to term, only 7.6 per cent of the operations, or 1 in 13.2 operations, resulted in a full term baby. Among the remaining 9 gestations, there were 6 abortions and 1 ectopic pregnancy. The outcome in 2 cases was unknown. In Von Graft's collected series of 41 cases in which an ovary was transplanted into the uterine cavity, only 3 pregnancies (7.5 per cent) resulted, of which 1 went to term (2.4 per cent) and the other 2 ended in abortion. Reiprich collected 200 ovarian transplants of all types and reported only 5 pregnancies (2.5 per cent) following these operations. Estes followed up 27 of 88 patients on whom he had performed his ovarian transplantation operation and found that pregnancy had occurred in 4 of them (15 per cent). In a later article, Estes reported that in a series of 50 patients whose case records were complete, only 4 became pregnant (8 per cent). Two of these women had abortions and 2 had full term babies.

No one has ever reported the transplantation of a tube or tubes from one woman to another, but transplants of ovary from one woman to another (homoplastic operations) have been made many times. In practically every instance the ovarian tissue was transplanted in order to prevent or overcome the distressing symptoms of the menopause.

As far as is known, the only case on record in which an ovary from one woman was transplanted into another and the latter became pregnant and gave birth to a living child was that reported by Robert T. Morris (*Med. Record N. Y.* **69:**697, 1906).

The chances of success in this case are so slight that an operation is not justified. Certainly if the patient is more than 35 years of age the idea of an operation should not be entertained.

DEXEDRINE

***To the Editor:*—What is the danger of using "dexedrine" for weight reduction? I believe I patient has diabetes produced by this drug. I do not prescribe it.**

G. Raymond Johnson, M.D., Ottumwa, Iowa.

Answer.—Dexedrine is *d*-desoxyephedrine, a drug whose actions are qualitatively similar to those of amphetamine. Quantitatively, the drug has somewhat more central stimulating action and somewhat less circulatory action than amphetamine. In common with other sympathomimetic agents, *d*-desoxyephedrine can produce an increase in blood sugar level, which may be sufficient to result in a transient glycosuria. Evidence that use of the drug produces diabetes does not exist. If given to a person already suffering from the disease it may aggravate symptoms. Diabetes is a contraindication to its use.

The Council on Pharmacy and Chemistry has recognized amphetamine and *d*-desoxyephedrine as adjuncts in the treatment of some cases of obesity. These drugs may depress gastric motility, thus allaying the sensation of hunger and making it easier for the obese person to follow a rigid dietary regimen. Furthermore, the central action of these drugs may assist in overcoming certain depressive states which, in some patients, may be responsible for overeating. These drugs should not be used routinely in the treatment of obesity. Patients to whom they are administered should be closely observed by the physician for possible untoward effects.

METALLIC PINS FOR FEMORAL NECK

***To the Editor:*—Discuss reasons why pinning of fractures of the neck of the femur by metallic pins, such as the Smith-Petersen nail, results in anatomic failure. When a patient leaves the operating table with the head and neck of the femur in perfect anatomic alignment, why will these show dislocement three weeks later although the patient has been kept in bed without a cast?**

M.D., Illinois.

Answer.—It is assumed that "results in anatomic failure" means: a displacement of fragments at the fracture site after what was thought to be perfect anatomic alignment resulting in incomplete apposition in one or more planes, angulation, separation; rotation of the head of the femur and untoward change in the angle of the neck of the femur, and/or with possible cutting through or retraction of the fixation nail. The reasons for any one or a combination of these subsequent findings may be listed in order of importance.

Failure to effect complete reduction of fragments and kissing coaptation of head onto trochanteric portion as shown by roentgenograms in at least two planes, anteroposterior and lateral: Even in a supposedly good reduction in the anteroposterior plane the cortical edges of the head and trochanteric fragment may not perfectly align; the lower cortical edge of the trochanter often overlaps or rides up under the edge of the capital fragment, thus interfering with reduction of the trabecular lines of the calcar femorale and possibly causing tilting or angulation of the head, which will slip further out of place very easily (and possibly lead to nonunion). This fault is often a result of failure to secure a sufficient amount of internal rotation of the femur.

Failure of the nail to penetrate sufficiently deep into the head of the femur: The pin may have been too short, or an unhappy angle of introduction of the nail through the trochanteric portion of the bone into the head may have occurred. The pin must skirt along the inferior cortical margin of the trochanteric portion and pass obliquely up into the head.

Failure to use a preliminary guide wire which penetrates and gently fixes the head after complete reduction in all planes: When such a guide wire is not used, the forceful driving in of the nail, as it reaches the fracture plane to pass into the head, may cause the head to angulate or rotate during its penetration.

Failure to check the position of fragments and nail by roentgenogram in at least two planes immediately after the nail is inserted.

Failure to impact the completely reduced fracture surfaces after the pin is inserted.

Multiple attempts to insert the nail: Its withdrawal and reinsertion may break down the cortical bone surface of one or both fragments, so that the bone does not hold well and permits angulation or rotation on slight motion or too early use of leg later, while the patient is lying in bed.

Failure of proper support or immobilization of leg after the most careful nailing: The leg may be supported in a Thomas leg splint in enough suspension in internal rotation to hold its weight off the surface of the bed and with continued skin traction to aid this without pulling the fragments apart, or the patient may be placed in a body plaster of paris spica for four to six weeks to insure support of the leg in the correct position during the early stages of healing. Many surgeons have returned to this wise course of postoperative fixation by external splint

Failure of careful postoperative supervision. Allowing the patient too much active motion of the limb, unguarded rough handling in nursing care or use of the bedpan, thus causing twisting and rotation of the limb especially outward, leads to strain on the nail support, which is exceedingly weak across the fracture plane

Failure to furnish a properly supporting nonsagging bed surface or to force the patient too early into a sitting position, with the leg lying unsupported.

Failure of the nail to hold even though the insertion seems proper after complete reduction and good aftercare, because the bone is atrophic or highly demineralized and the holding friction against the surface of the nail is almost nil from the start

Most troubles of this nature result from incomplete reduction imperfectly checked by roentgen ray and/or lack of suitable postoperative fixation and control The operator must not allow himself to be satisfied short of complete check on all the factors mentioned, and the work must be done by one who is thoroughly qualified.

SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

To the Editor.—Now that penicillin is becoming accepted in the treatment of syphilis of the central nervous system and numerous authors have confirmed the excellent results obtained with fever treatment in conjunction with penicillin, what is current opinion on the advisability of chemotherapy following fever and penicillin treatment

I refer to cases of syphilis of the central nervous system in patients with psychosis who must be hospitalized for fever treatment. Latest opinion seems to favor observation of these patients for a two year period without giving arsenic and bismuth preparations if the spinal fluid findings continue to be favorable This treatment appears indicated if there is a reversal in the spinal fluid formula when chemotherapy is begun. Is it still not advisable to give intensive chemotherapy to such psychotic persons, in addition to fever and penicillin, regardless of the improvement which may be observed in the two year period of observation of the spinal fluid formula?

Dr. Dattner, Dr. Curtis of the Rochester group, Dr. Stokes of Pennsylvania and Dr. Moore of Johns Hopkins maintain that "retreatment" should be recommended if a "relapse" is indicated What should be considered "a relapse" and what is the latest consensus concerning the use of tryparsamide in routine treatment of syphilis of the central nervous system? I understand that Dr. Stokes in 1944 stated definitely that it did not accomplish more than routine trivalent arsenic does.

I refer in the foregoing to cases of syphilis of the central nervous system without adequate chemotherapy preceding fever and penicillin treatment. If the patient had had adequate chemotherapy prior to such institutional treatment further chemotherapy may be of questionable value. However, in the absence of such previous chemotherapy, a two year course of chemotherapy appears indicated just as long as the spinal fluid formula has not completely returned to normal As penicillin and fever treatment, without routine chemotherapy, has not been used for a sufficient period to be able to say that patients may not relapse years afterward, it would seem to me that one is not yet warranted in assuming that the future outlook for these patients may not be jeopardized by the failure to give routine chemotherapy after fever and penicillin.

M.D., California.

Answer.—The consensus among authorities before the introduction of penicillin was that chemotherapy should be used following fever therapy of paresis (Moore, J. E: The Modern Treatment of Syphilis, ed 2, Springfield, Ill., Charles C Thomas, 1941). In this country tryparsamide and bismuth preparations were usually given over a minimum period of two years. Tryparsamide was used because of the evidence of the inefficacy of trivalent arsenicals in paresis. Bismuth was used to help control syphilis outside the central nervous system because of the evidence that activity of such lesions might occur in patients whose paresis had been controlled by fever therapy. In patients who had had little or no chemotherapy preceding the induction of fever, courses of trivalent arsenicals were frequently also administered to help control syphilis outside the nervous system.

An authoritative opinion with regard to chemotherapy following the administration of treatment of paresis is given in Moore's monograph (Moore, J. E.: Penicillin in Syphilis, Springfield, Ill., Charles C Thomas, 1947). Authorities in this field with few exceptions have not advocated chemotherapy with arsenic and bismuth compounds after the administration of penicillin and fever, even though it is true that sufficient time has not elapsed to be sure that improvement in paretic patients will be in general well sustained.

There are several reasons for the change in attitude regarding prolonged arsenic-bismuth chemotherapy. 1. It is already clear that favorable effects of penicillin on lesions of late syphilis are not principally limited as with fever therapy to the central nervous system. 2. There is increased skepticism concerning the real effectiveness of tryparsamide in syphilis of the central nervous system. While the effectiveness of tryparsamide in paresis has not been adequately reinvestigated in recent years, studies such as that of Hahn and Clark (Hahn, R. D., and Clark, E. G.: Asymptomatic Neurosyphilis: Prognosis, *Am. J. Syph., Gonor. & Ven. Dis.* **30**:513, 1946) have emphasized the possibility that the effectiveness of tryparsamide in syphilis of the central nervous system has been overrated. 3. The influence of the Dattner-Thomas concept (Dattner, B.; Thomas, E. W., and Wexler, G.: The Management of Neurosyphilis, New York, Grune & Stratton, 1944) of spinal fluid changes associated with activity and inactivity of syphilis of the central nervous system has been felt. These workers, who had argued against the necessity of prolonged postfever chemotherapy in the treatment of paresis even before the introduction of penicillin, have advanced the concept that while pleocytosis, increased protein and abnormal colloidal test curves are associated with activity of the syphilitic process, positive serologic tests without abnormalities in protein and cells are not associated with activity. While it is true that many authorities are not willing to accept this concept as an invariable rule, it has certainly had considerable influence against the use of chemotherapy following penicillin-fever therapy of paresis.

All authorities advise close follow-up of treated paretic patients. Spinal fluid examinations should be done every six months for two years and preferably every three months during the first year. Indications for retreatment are unsatisfactory clinical improvement after six months' observation, clinical relapse or relapse in spinal fluid abnormalities. The prognosis of patients in whom retreatment is necessary is frequently poor. This is particularly apt to be true if in the first treatment the full course of fever (forty or more hours of fever over 104 F.) and high dosage of penicillin (6,000,000 units of penicillin or more over a period of fifteen days or longer) were employed.

In retreatment, fever therapy should be used, particularly if the previous fever therapy was inadequate, and penicillin dosage should be doubled and given over a longer period of time. Penicillin therapy may succeed the second time in spite of a previous failure, as is the case with early syphilis; tryparsamide therapy could also be given.

"SYNTROPAN"

To the Editor:—Please discuss "syntropan" (phosphate salt of 3-diethylamino-2, 2-dimethyl-propanol tropic acid ester) as an aid to dilatation of the cervix in the first stage of labor. Has the drug shown clinical benefit in shortening the first stage of labor?

Arthur Whitlatch, M.D., Milan, Ind.

Answer.—J. E. Stoll (*Am. J. Obst. & Gynec.* **42**:473-477 [Sept.] 1941) maintained that "syntropan" had a definite antispasmodic action in labor. In the patients on whom he used this drug, labor was on an average about one half as long as in the control patients. R. Cron, E. A. Banner and W. F. Hovis (*ibid.* **45**:295 299 [Feb.] 1943) found that there was only six minutes difference in the length of the first stage in women treated with "syntropan" and in the controls.

J. A. Wells, D. D. Albers and A. C. Ivy (*ibid.* **46**:222-229 [Aug.] 1943) performed animal experiments with the drug. They state, "The implication found in the clinical literature that syntropan hastens cervical dilatation by relaxing the cervix does not receive support from the present observation that this drug does not relax the cervix of the postpartum dog. . . . In all probability, cervical dilatation is a physiologic adjustment to the presenting part, and is accomplished by effective contractions of the body of the uterus. Therefore it would appear that hastening of cervical dilatation might best be accomplished by a drug which increased the effectiveness of the contractions of the body of the uterus."

VAGINAL SMEAR CANCER TEST

To the Editor:—It has been called to my attention that Dr. Joseph V. Meigs of the Harvard Medical School of Boston and Dr. J. Ernest Ayre of the Royal Victoria Hospital of Montreal, Canada, have done some work on cytology along with Dr. George N. Papanicolaou of the Cornell University Medical College of New York in connection with the early diagnosis of cancer, particularly uterine cancer, by an examination of a vaginal smear. Is this an acceptable method of the diagnosis of cancer?

Norman H. Smith, M.D., Minneapolis.

Answer.—The vaginal smear is apparently an accepted method of diagnosis of cancer of the cervix and ought to be accurate anywhere from 95 per cent to 100 per cent; the method is accurate in only about 80 per cent of cancers of the endometrium or body of the uterus. There are too few pathologists trained to perform a cytologic examination properly, and more should be thoroughly trained. Eventually cytologic diagnosis will fall into the same category as the diagnosis of tuberculosis of the kidney or of the lungs and also the Wassermann test.

KHELLIN

To the Editor:—What is the information on the use of Khellin in the treatment of bronchial asthma? This was recently mentioned in *Cosmopolitan* magazine and in *Collier's*.

M.D., Illinois.

ANSWER.—Khellin is one of several active principles obtained from Ammi visnaga Lam., an umbelliferous plant indigenous in the countries around the Mediterranean, whose fruits, under the name khella, have long been used in Egypt in the treatment of ureteral spasm and kidney stone (U. S. Dispensatory, 1943).

Khellin ($C_{14}H_{12}O_5$) is mentioned in the abstract (THE JOURNAL, June 28, 1947, p. 835) of the report of Anrep and his associates on Ammi visnaga for the anginal syndrome, published in the *British Heart Journal*, October 1946, page 171. These investigators, reporting from the Physiological Laboratory and the University Hospital, Cairo, Egypt, stated that the crystalline preparation of khellin which they used was obtained from Professor K. Samaan of the department of pharmacology of the University of Cairo and from the Physiological Laboratory of this institution. An early report by Samaan appears in the *Quarterly Journal of Pharmacy and Pharmacology*, London, 1932, page 6; a preliminary report by F. A. Upsher Smith of Ammi visnaga appears in the *Journal of the American Pharmaceutical Association*, March 1933, page 184; the U. S. Dispensatory also provides a brief discussion of the drug.

Apparently the drug has recently been used experimentally in the treatment of asthma and also as a coronary vasodilator. A brief note in *Lancet* (London), May 17, 1947, page 682, is concluded with the following paragraph:

"That khellin may have further uses is suggested by the observation that after a single intramuscular injection of 200 to 300 mg. 'complete and prolonged relief' was obtained in 41 of 45 patients with severe bronchial asthma; and even this fairly large dose had no effect upon the blood pressure. It has, moreover, relieved attacks resistant to adrenaline and aminophylline. Whether, as suggested, khellin is safer than aminophylline is not yet certain, for experience with it is so far small. If, however, khellin is to come into general use preparations of it must be purified and standardized, for there is some evidence that the impurities in Ammi visnaga may be toxic."

These reports, though promising, do not provide adequate evidence on which to base a satisfactory evaluation of the therapeutic worth of khellin in the management of asthma, and until further confirmatory studies with suitable controls become available the status of the drug must be considered to be in the experimental stage.

Information is not available to show that khellin or any other active principles of Ammi visnaga are available commercially in this country, nor is there knowledge of any efforts which the Egyptian Chemical and Drug Industries of Cairo, apparent promoters of the drug, may have made to secure the introduction and therapeutic trial of its preparations "visammimix" and "khellinin" in the United States.

RETCHING AND ARSPHENAMINE

To the Editor:—What will prevent retching after intravenous arsphenamine treatment?

S. Englander, M.D., Cleveland.

ANSWER.—Retching after an intravenous injection of arsphenamine is not a common complaint. It might be due to a psychic effect rather than the arsenic. Eating of peppermint candy at the time of the injection is said to be of help. Otherwise, it would seem that a small dose of sodium bicarbonate would be sufficient.

SLUDGING OF BLOOD

To the Editor:—Have observations been published regarding the combined use of anticoagulants and penicillin in infectious diseases? In view of recently published studies on the sludging of blood in the arterioles in infectious diseases would not such therapy appear to be a logical conclusion? Is it possible by improving circulation in the capillary bed with anticoagulants to enhance distribution of penicillin? In infectious diseases in which anticoagulant therapy was used because of concomitant thrombophlebitis it was my impression that the combination therapy shortened the illness.

Fritz F. Blumenthal, M.D., Middletown, N. Y.

ANSWER.—Thus far nothing has been published regarding the combined use of anticoagulants and penicillin in infectious diseases. It would seem theoretically that such a method of treatment might be advantageous because of the sludging of blood in the arterioles which has been reported to occur in a number of acute infectious diseases. If an anticoagulant was to be given in the manner that you suggest, it would undoubtedly be necessary to administer it early in the course of the infection. Further studies may confirm the impressions that you hold in this respect.

"PITRESSIN TANNATE"

To the Editor:—Please comment on the feasibility of "pitressin tannate in oil" for the treatment of hypertension, as advocated by Dr. John Q. Griffith of Philadelphia. Likewise, his recommendation of roentgen radiation of pituitary. Is the clinical evaluation which he places on bioassay of urine in hypertensive persons valid? For instance, is the high incidence of what he calls "excess amount of anti-diuretic principles of post pituitary gland" in hypertension as common as he claims? Can "pitressin tannate" be used in hypertensive heart disease accompanied by coronary sclerosis with safety? Is the clinical evaluation which he places on plasma creatinine physiologically sound? Explain the clinical use of rutin.

M.D., N. Y.

ANSWER.—The theoretic concept applied to justify the use of "pitressin tannate in oil" in the treatment of hypertensive disease is based on several only partially validated assumptions. It is conceived that the introduction of beta-hypophamine ("pitressin") depresses the secretion of the pituitary and that such depression may persist following withdrawal of the injected, additional hormone. There is, however, no assurance that such injections may not aggravate the situation. "Pitressin tannate" should not be employed in the presence of detectable coronary sclerosis, anginoid symptoms, retinitis, pregnancy or impaired renal function. These are definite contraindications. The indications are much more vague.

Radiation of the pituitary in hypertensive disease is not a new procedure. It was advocated by Hutton in 1934 (Hutton, J. H.: *Illinois M. J.* **66**:120 [Aug.] 1934) and since then has been periodically in vogue with a few clinicians. Rationale is based on an assumption whose validity is open to considerable doubt. Bioassay of pituitary pressor substance in either blood or urine is as yet not sufficiently sensitive to be satisfactory; the antidiuretic principle can be assayed, and it is assumed that *variations in the content of antidiuretic principle reflect parallel* variations of the pressor principle. It is notable that many patients with demonstrable hyperfunction of the posterior pituitary do not have hypertension; similarly, diabetes insipidus is not characteristically associated with either hypertension or hypotension. (Pendergrass, E. P.; Griffith, J. Q., Jr.; Padis, N., and Barden, R. P.: Indications for Irradiation of the Pituitary Gland in Patients with Arterial Hypertension, *Am. J. M. Sci.* **213**:192 [Feb.] 1947).

A fairly exhaustive search of recent literature indicates that there is no convincing confirmation of the clinical values of bioassays of the urine in hypertensive disease. It is extremely doubtful, in view of observations made in connection with diabetes insipidus as well as hypertensive disease, that excessive amounts of antidiuretic principle are common.

Rutin has definite value in diminishing capillary fragility, which is often increased in hypertensive disease because of the histanoxia due to reduced capillary flow distal to constricted arterioles. (Griffith, J. Q., Jr.: Increased Capillary Fragility in Hypertension, *Am. Heart J.* **28**:758 [Dec.] 1944). It is indicated only when testing reveals definitely a capillary fragility (Griffith, J. Q., Jr.: *Proc. Inst. Med. Chicago* **16**:434 [Oct.] 1947). The evaluation of clinical results with rutin is extremely unsatisfactory, because the major purpose is the prevention of capillary hemorrhage and therefore control studies are not feasible. Increased capillary fragility is not uncommon in states other than hypertensive disease: infection, fatigue, menstruation and allergic reactions (Brown, E. E.: Diseases Associated with Low Capillary Resistance, *Am. Heart J.* **34**:241 [Aug.] 1947). In cases in which extreme hypertension exists, or when the hypertensive presents coincident infection, allergic reactions or excessive fatigue, it should be useful in reducing the probability of capillary hemorrhage, particularly in the brain, retina or kidneys.

It should be emphasized that arterial hypertensive disease is a disorder with many etiologic factors and that the causative factors are not necessarily the same in any two cases. Control therapy, as well as curative or prophylactic therapy, must be based on individual etiologic analysis as far as possible. No one will discover a universal single cause for hypertension; there are always many contributing causative factors, not the least of which is hereditary vulnerability of the vascular structures. Treatment must be as individualized as etiology, and it must not be forgotten that with hypertension, as with most other disorders, it is much more important to treat the patient who has the disease rather than to treat the disease and ignore the patient.

MEDICAL PROBLEMS OF THE MILITARY ESTABLISHMENT

MAJOR GENERAL MALCOLM C. GROW
THE AIR SURGEON
Washington, D. C.

From the War of 1812 until the present time, the wooden and later iron and steel walls of the British and American fleets have stood between our heart land and the aggrandizements or military threats of any potential enemy. Neither the Central Powers in World War I nor the Axis nations in World War II were able to breach these barriers or approach our continental installations and resources, wherein lie the bulk of our military potential. This unchallenged security, based on our position of relative geographic immunity, encircled and protected by a ring of steel, has perhaps engendered an attitude of domestic complacency, a complacency which may, for the first time, have been jolted a bit, simultaneously with the realization of the devastation wrought by the atomic bomb bursts at Hiroshima and Nagasaki at the conclusion of World War II. Just as the massed infantry assault tactics and tremendous personnel attrition of the early years of World War I were gradually replaced by the infiltration operations of the final campaigns, which represented the precursor of the type of action which characterized the early operations of World War II, so the air offensives and the atomic bomb which foretold the doom of Germany and Japan represented the fullest fruition of the alliance between scientific and military thinking, and simultaneously furnished us with a realistic pattern through the application of which we may anticipate the scope and magnitude of the first campaign in any subsequent war. The effective range of modern aircraft types are already surpassing the 1,600 mile action radius of the B-29, while currently planned aircraft, to be delivered in the not too distant future, will probably bring all of the inhabited areas of the earth within the striking range of the several major potential belligerents. No area and no city may then consider itself immune from the effects of atom bombing. Our seaboard cities are particularly vulnerable, since this new weapon of destruction may be delivered with equal effectiveness by a tramp steamer at dockside or from an aircraft flying overhead. Only one who has seen the ruins of the atom bombed cities of Japan and who has examined the casualty studies which were done there can begin to imagine the damage and loss which would be sustained if a dozen of our major ports were simultaneously attacked in this manner.

New methods of warfare demand new and better preparations for defense. Certainly the British, and afterward the Germans, in World War II, prepared themselves for the incendiary and explosive bombing which was expected to materialize as aircraft production expanded. Yet the British were hard put by the raids on London and Coventry and the German defense organization was overwhelmed by the concentrated weight of bombs which fell on the cities of the Ruhr valley, Berlin and especially Hamburg. We should have to multiply this destruction a hundred fold in order to approximate the magnitude of the disaster which would be associated with the detonation of an atomic bomb in New York, Washington or Chicago. Of course, many of those injured by radiation emanations could not be saved, since eventual, although not immediate, death is the inevitable consequence of a lethal dose of gamma particles; nevertheless, all living casualties must be screened in order that therapeusis may be concentrated on those irradiated persons whose prognosis is eventually favorable, or at the worst, doubtful. Furthermore, those persons receiving lethal doses of radiation would require palliative treatment and nursing care. I do not believe that the medical means to cope with such disasters could be organized on a voluntary basis. To underwrite the efficient utilization of the available doctors, nurses and medical supplies in the face of damaged transportation and communication systems would require definitive action on the part of a central civilian medical authority closely associated with a civilian defense organization, the latter

---

Read in a Panel Discussion before the regular session of the Council on National Emergency Medical Service of the American Medical Association at Chicago, April 6, 1948 being empowered to mobilize and direct the entire civilian defense potential. Some assistance might be expected from the military. The Air Force in particular might furnish air evacuation and air transportation for medical supplies and personnel. However, it is necessary to assume that the National Defense Establishment, together with its medical military components, would be engaged in retaliatory action against the enemy to the limit of its capabilities, and consequently would be unable to render extensive direct support to the civilian population. To require more assistance from the armed services would weaken our offensive effort and so invite and encourage more extensive enemy action directed at the destruction of our resources, our industries and our will to resist.

Yet I do not propose that the medical services of the armed forces divorce themselves entirely from the civilian economy and permit our homeland to defend itself as best it can. Instead, there is one major contribution which the military medical service may make to the betterment of the civilian welfare in anticipation of such emergencies. Our contribution would consist of the application of a rigid economy in the employment of doctors and allied specialists. During World War II, approximately one third of all the doctors in the nation were utilized by the armed services to furnish medical care for approximately one tenth of the population. In a future war, the hazards associated with civilian existence may approximate those of soldier, sailor and airman. It is only reasonable, then, that the standard of our medical care, together with the aggregate of our medical resources, should be divided more equally between the civilian and military components. The risks to be incurred by services must be evaluated against the casualties which may be expected in the civilian population, and our medical means must be balanced on this comparison. The National Security Resources Board, established by Public Law 253, represents an agency wherein civilian and military leaders from the highest levels may explore and develop the medical requirements of the military and nonmilitary categories. It would be most desirable if a representative of the Council on Emergency Medical Service might be assigned to the Board to assist in the development of the civilian requirement for our medical resources and to insure participation of the American Medical Association in decisions which involve the health and welfare of the nation. The armed services may render no greater assistance to the National Security Resources Board and to medicine as a whole than through the practice of rigid economy in the authorization of medical officer assignments throughout the military structure. In general, I believe there are four methods through which the armed services may apply the principle of parsimony in the employment of doctors. These are:

ASSESSMENT OF REQUIREMENTS

First, the realistic assessment of medical officer requirements. Doctors were procured for the Army and the Air Force throughout World War II under the outmoded thesis that approximately six and a half physicians were required for each thousand troops serviced. This procurement objective was based on World War I experience, when large numbers of soldiers were employed on very limited ground fronts and bitterly contested each square foot of territory in a dogged war of attrition designed to destroy the manpower reserves of the enemy. Casualties were in consequence unprecedented, as were the demands on the medical services. World War II saw the evolution of a new military philosophy in which major efforts were directed at the destruction of the war-making potentials of the enemy, and particularly his industrial resources. Relatively fewer casualties were sustained when considered in the light of the scope of the actions involved. Had the effect of the strategic bombing of Japan been anticipated by the Medical Department of the Army, procurement of doctors against the casualty rates which were expected to characterize the invasion of Japan would have been unnecessary. Neither was enough cognizance had of the advancement of scientific methods in the practice of medicine. New biologic and chemotherapeutic drugs in combination with better immunization methods have reduced the incidence and simplified the treatment of a variety of medical conditions and illnesses which have previously been associated with the conduct of military operations in the field. At the same time, British experience in World War II indicates that adequate medical coverage can be afforded with the employment of a smaller ratio of medical officers. The procurement of medical officers in a subsequent emergency, if based on the actual medical requirement of the armed services rather than on an arbitrary ratio of six and a half doctors per thousand troops, would effect a most significant and obvious savings in the employment of physicians by the military establishment.

REPLACEMENT OF PROFESSIONAL OVERHEAD PERSONNEL

Second, the replacement of professional overhead by nonprofessional personnel. When the organizational pattern of the Medical Service is examined, it is apparent that a considerable number of medical officers are being employed in positions and are discharging responsibilities which are not directly concerned with the professional care of military personnel. This is particularly true at the higher staff levels and in the larger hospital installations. There are certain staff planning capacities in which the professional background is a necessary adjunct; however, a significant opportunity remains for the introduction of economy in the utilization of medical officers through the substitution of nonprofessional personnel for the doctors currently employed in hospital and other medical overhead administration. The rapid transportation of patients by air, where medical attendance by nurses and trained enlisted men suffices for the care en route because of the short duration of the evacuation interval, would render unnecessary the employment of large numbers of medical officers to staff the more slowly moving hospital trains and ships. At the same time, hospital manning tables may be evaluated in the light of the mission and actual capabilities of the unit with a resulting moderate saving in the professional categories.

DELAYED DEPLOYMENT

Third, the delayed deployment of the professional and specialist group. Throughout World War II, it was the custom to activate hospitals as complete units within the Zone of Interior for deployment to theaters of operations overseas. Once activated, the organization pursued a training program of several months' duration, in some instances with its authorized equipment, was shipped to a port of embarkation, processed there, transported overseas, disembarked, personnel and equipment assembled, perhaps retrained in the theater, again transported to its site of employment, set down and prepared to receive patients. Not infrequently a year elapsed between the departure of individual physicians from their native community and their readiness to utilize their training in the attendance of military patients. Yet all of this transitional and migratory activity on the part of the doctors can hardly be regarded as conducive to fostering their ability to provide medical care for the sick and wounded. This prodigal use of trained physicians could be corrected through the simple expedient of delaying the deployment of the professional groups. In practice, the system would operate in this fashion: With the announcement of mobilization, civilian physicians would be channeled through reception and classification centers where their background would be evaluated and their suitability for military duty determined. This processing would require no more than a week in the case of each individual physician, who would then return to his local community to continue in his practice, subject to subsequent call to duty. Meanwhile, the activation of hospital units and the assembly of their enlisted personnel and equipment would continue under the direction of nonprofessional military supervisors. The professional group would be assigned on paper prior to the departure of the unit for overseas, and not until then would the individual doctors be notified of the probable date of their commitment. The hospital would be shipped to the theater of operations with only a small fraction of its professional staff, the remainder of which would continue to remain in their local communities. On the arrival of the unit in the theater and on completion of its intratheater processing and transportation, the hospital would be erected at its site of employment by the nonprofessional echelon already assigned. Shortly before the anticipated date of the opening of the hospital, the theater commander would call on the Zone of Interior for the shipment of the professional staff, who would be transported to the theater by air or sea, arriving a few days prior to the actual opening of the hospital for the reception of its first increment of patients. The savings to be accomplished through the delayed deployment of the professional staffs and specialists in the case of hospital organizations are readily apparent.

IMPROVED EMPLOYMENT OF SPECIALISTS

Fourth, improved employment of the specialist categories. In the past, it has been the custom to distribute professional specialists among theaters of operations and the Zone of Interior in a manner which parallels the deployment of other medical officers, i.e., on the basis of troop strength in the area involved. In consequence, these persons were committed and assigned in anticipation of casualty and sickness workloads which frequently failed to materialize. Wastage of their professional skills and time were inevitably associated with the practice of identifying these persons as intrinsic components of specific theaters, regions or units. Such wastage could hardly be obviated without a major revision of operating procedures. Recognition of the specialist as a distinct entity in the organizational sense would correct this condition. Small teams or even individuals might be designated as reenforcements for regional or unit staffs, and shuttled within a theater, between theaters or between theaters and the Zone of Interior by air or other rapid transportation as the actual need for specialists developed. This plan, while not new, was never implemented because the creation of special groups not subject to the general policies with regard to the duration of the overseas tour is always opposed from the point of view of personnel administration and favoritism. However, if the shortage of the specialist categories is as serious as has been emphasized in certain quarters, it would appear that these considerations are of a magnitude sufficient to warrant the special handling which is proposed for this group.

If these economies which I have mentioned are accepted and implemented throughout the armed forces, or others of a similar nature, it is my belief that the services will never again be accused of wasting doctors, dentists or nurses in any subsequent emergency and will not be overstaffed with medical talent at the expense of the civilian population.

While I have discussed a number of the considerations bearing on medical service in the military establishment, I should prefer to make no recommendations with respect to the type of medical organization which should be associated with the civilian defense agency. It is apparent, though, that its successful operation would doubtlessly require a form of universal service applicable to the medical profession, a subject which would better remain in the capable hands of the American Medical Association and, specifically, the Council on Emergency Medical Service. The implications of such a compulsory system are staggering and even frightening, yet in the last analysis they are not so far removed from the selective service that we knew in World War II.

CONCLUSION

I should like to mention the activities of the Hawley Board in connection with the organization of the medical service in the National Defense Establishment. For some months the Board has been concerned with the development of a more efficient system for the medical care of our military components. I believe that substantial economies may be demonstrated through the application of the principles of joint and cross servicing in the fields of medical meteriel and personnel procurement, through the utilization of research and training facilities and through the elimination of duplicating hospital installations. At the same time, it is apparent to all that the efficient medical support of Army, Navy or Air Force in actual combat requires the close identification of the operating elements and components of the medical service with the command structure of the major force involved. The establishment of an Air Force medical service to provide the troop unit and station level medical attendance required by the Air Force and to participate jointly with the medical departments of the Army and Navy in the operation of the larger hospital installations and various medical overhead functions would be the logical corollary of this concept. Certainly the recommendations of the Hawley Board will embrace a number of revolutionary changes, all of which, I hope, will represent steps toward the creation of an efficient and attractive medical establishment within the armed forces which will reflect the fine tradition and ever superior standards of American medicine.

Second Era of Research in Chemotherapy.—During the past dozen years we have all witnessed the impact on medicine of what Sir Henry Dale has called the second era of research in chemotherapy, as manifested practically in the unparalleled usefulness of the sulfonamides, penicillin, and the newer antimicrobic drugs, and theoretically in the impetus which their discovery has given to new thought and experimentation on the metabolism of parasitic cells, the mechanisms of drugfastness, and the general principles of chemotherapy. Great as these achievements are, they were exceeded, in my opinion, by the attainments of bacteriology in the final quarter of the 19th century.—Kidd, John G., *Bulletin of the Johns Hopkins Hospital,* June 1948.

ROENTGEN DIAGNOSIS OF MYOCARDIAL INFARCTION

L. HENRY GARLAND, M. D.
San Francisco
and
S. F. THOMAS, M. D.
Palo Alto, Calif.

The clinical diagnosis of major infarction resulting from coronary insufficiency or occlusion is usually reliable, especially when confirmed by the presence of suitable electrocardiographic changes, slight fever, leukocytosis and an increased sedimentation rate.[1] However, there are some cases in which the clinical diagnosis is in doubt and in which additional data are desirable or essential for confirmation. Such cases include those with (*a*) an indefinite or atypical history, with or without positive electrocardiographic findings, (*b*) a definite history but negative or inconclusive electrocardiographic findings and (*c*) no definite history but apparently positive electrocardiographic findings.

Infarction in the "acute" stage is essentially a problem for clinical diagnosis; the patient can rarely be moved for roentgen studies and the electrocardiogram is usually positive. Infarction in the healing or "healed" phase is often a problem for joint clinical and roentgen examination; the electrocardiogram has not infrequently reverted to normal or become nondiagnostic.[2] It has been estimated that about 18 per cent of patients with verified coronary occlusion have negative electrocardiographic findings, as such are ordinarily made and interpreted.[3] It is in this group particularly that kymographic examination may be of value.

In view of the fact that "coronary artery disease, with the possible exception of cancer, is now responsible for more fatalities than any other disease",[4] the vast import of infarction is apparent. That infarction is no respecter of age is illustrated by Newman's recent report of a series of 50 cases of

coronary occlusion occurring in young robust adults under 36 years of age (all but one of them male); most of these cases showed extensive myocardial damage.[5] In this age group the kymographic method can be a most useful adjunct in diagnosis

METHOD

Roentgen examination of the heart for the determination of myocardial damage involves fluoroscopic and roentgenographic examination and, in some instances, roentgen cardiac kymography. The fluoroscopic detection of severe myocardial damage is not difficult, but is prone to the limitations of subjective impression and provides no record which may be reviewed at a later date or studied by others. Sosman, Levene and others have ably described the criteria for the fluoroscopic diagnosis of heart disease, and full information can be obtained from their publications. The silhouette is studied as to size, shape, position and motion. Areas of myocardial damage are suggested by localized abnormalities of curvature and motion (flattening and diminished excursion of the ventricular wall or, less commonly, bulging and paradoxic expansion).

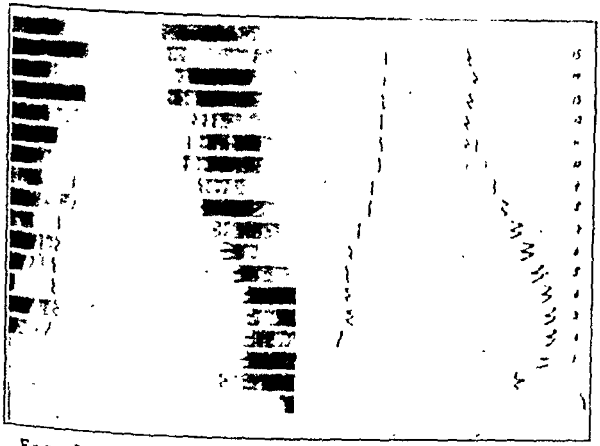

Fig. 1.—Roentgenkymogram of healthy adult 30, with tracing to illustrate the various types of waves normally present over the cardiovascular silhouette. The numbers refer to the individual "frames" above the left hemidiaphragm: 15 to 10 on left of tracing, pulsations of superior vena cava, 9 to 5, right auricle, and 4 to 3, right ventricle; 15 to 12 on right, descending aorta; 11 to 10, pulmonary artery; 9, ascending aorta, and 8 to 1, left ventricle. Posteroanterior view.

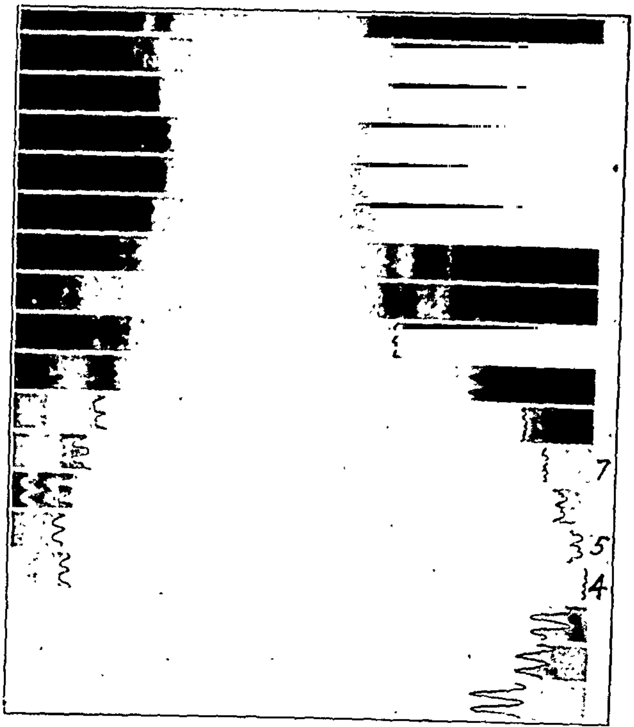

Fig. 2.—Posteroanterior kymogram of man aged 46. Note absence of normal waves in frame number 4 above the left hemidiaphragm ("silent" frame); and the reversed pattern in frames 5 to 7 ("paradoxic" motion). Roentgen diagnosis was myocardial damage, presumably infarction, involving the wall of the left ventricle. The patient was a physician with a clinical diagnosis of infarct, but questionable electrocardiogram. Autopsy verification three weeks later.

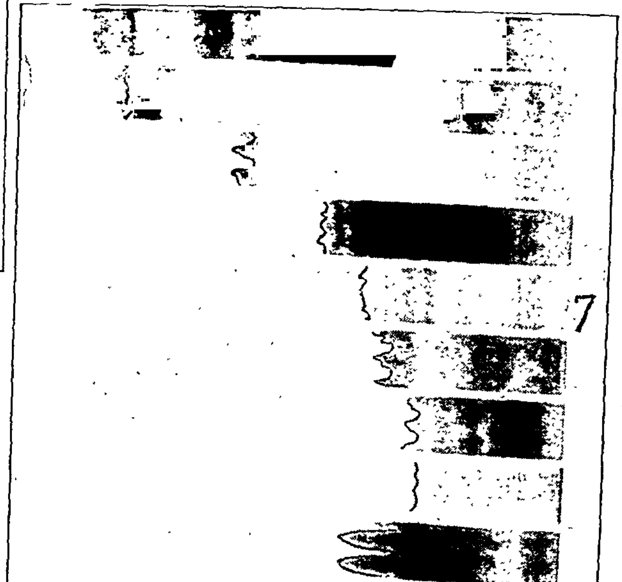

Fig. 3.—Same kymogram as in figure 2.

Cardiac kymography is usually performed with the multiple slit kymograph, using 12 to 1 grid ratio. Films are made in whatever projection is deemed most liable to demonstrate the involved area of myocardium, usually in the posteroanterior and left anterior oblique positions; occasionally in right anterior oblique (left anterior oblique, 65 degrees; right anterior oblique, 45 degrees). Technical factors vary with the patient's build and pulse rate; most cases are satisfactorily handled with these factors: 85 kilovolts, 100 milliamperes, 48 inch (121.9 cm.) target-film distance, one and one-half seconds' time, moderately deep inspiration. In questionable cases the film may be repeated, perhaps in a different phase of respiration, or with the slits turned to an angle other than the horizontal. Frames with diminished, absent or paradoxic ventricular waves are usually indicative of myocardial disease.

ROENTGEN KYMOGRAPHY

Roentgen kymography is a method for recording the movements of an organ on a single film. There are several possible technics, but we will confine our remarks to multiple slit kymography at this time. The electrokymograph of Henny and Chamberlain[6] may offer aid in this problem, but to date its value in clinical work is still unpublished.

Multiple slit kymograms are records of one component of the movement of the organ under survey, the only motion accurately registered being that which occurs in a direction parallel to the slits. By turning the slits to various angles one may record the motion of different portions of the organ. For purposes of myocardial wall study, horizontal slit kymograms are usually adequate, since the majority of infarcts occur in those portions of the ventricles which are near the anterior interventricular groove. Even when not located near the left cardiac border, infarcts tend to cause variable degrees of "splinting," with restricted or irregular contractions of that border, and such abnormal contractions are usually detectable in routine posteroanterior kymograms.

The individual kymographic waves are examined as to amplitude, shape and timephase. The amplitude and shape of ventricular waves normally show wide variations, and therefore apparent alterations must be critically evaluated.[7] This applies especially to waves near the apex, where, owing to occasional predominance of vertical over horizontal contractions, motion may seem to be absent in healthy persons.[8] Timephase is best studied with the aid of calipers; the peak of a diastole or the valley of a systole may be measured from the base of the frame under review and that distance compared with other frames over the ventricular outline. Since the visible evidence of ventricular systole appears first at the base and progresses downward to the apex, the timing or phase of ventricular waves varies a very slight amount over the ventricular border.

If serial films are made for comparison, it is essential that they be made in identical phases of respiration, with similar time exposures and with smoothly moving films, since the shape and amplitude of the waves are profoundly influenced by variation in these factors.

The amplitude of ventricular wall movement is diminished in myocardial disease (including infarction, pronounced enlargement, hypothyroidism, thiamine deficiency, severe infections and cardiac neoplasm), and in certain pericardial disorders (effusion and adherent scars). A negative kymogram does not exclude the presence of an infarct. The most reliable positive kymographic sign of infarction is the presence of either paradoxic motion or an immobile area between two zones of normal motion. The most common signs are systolic expansion and absence of motion over the lower half of the left ventricular border. When limited to the apex, this should be confirmed by films made in other positions or in expiration or on succeeding days. Restricted movement at the apex alone may be due to physiologic variation in the direction of contractions.

Concerning identification of the probable area of infarction, Dack and others[9] offered the following comments relative to cardiac anatomy:

> The superficial muscle layers are attached to the auriculoventricular ring posteriorly, and wind around the left ventricular margin and apex to the anterior surface, where they are inserted in the papillary muscles. It is possible to speculate that infarction or scarring posteriorly will deprive the spirally arranged muscles of their posterior fulcrum, and therefore the portion of the muscle in the apical region or along the left ventricular contour gives way with each systole of the heart, and passively expands or remains stationary instead of contracting.

For this reason, perhaps, the area of "infarction" in the kymogram does not always coincide with the postmortem location of the infarct.

A "positive" kymogram may occasionally be found in patients with no clinical symptoms of myocardial infarction. This may be due to the presence of a silent infarct, or, occasionally, to unexplained physiologic variations in cardiac movements; myocardial tumors and localized adherent pericardial scars may cause similar changes. The differential diagnosis of extensive infarction from diffuse myofibrosis or muscle infiltration may be impossible on kymographic grounds alone. Generalized diminution of contractions and other changes may occur in all these conditions. However, localized infarction will usually show localized alterations (especially systolic expansion) which are relatively characteristic. Areas of infarction have been followed for periods of several months and seen to return to normal pulsation in some cases—which is plausible in view of clinicopathologic opinion that about 25 per cent of infarcts heal completely. Sussman[10] reported such change in 17 per cent of a group followed for two years. Penner and Peters[11] reported a case of proved ventricular aneurysm in a man of 43 who survived fifteen years!

[7] Thomas, S.F., and Garland, L.H.: Roentgen Cardiac Kymography, California Med., to be published.

[8] As part of an investigation of cardiac size and output in healthy persons conducted by Keys (Keys, A.; Friedell, H.L.; Garland, L.H.; Madrazo, M.F., and Rigler, L.G.: Roentgen Kymographic Evaluation of the Size and Functions of the Heart, Am. J. Roentgenol. 44:805-833 [Dec.] 1940) some years ago, one of us (L. H. G.) had the privilege of making a few hundred kymograms and seeing the analysis of several more, totaling in all about 500 persons. In approximately 5 of these cases silent or paradoxic frames were noted in some portion of the left ventricular area. These were never constant on recheck, and the amplitude of waves in adjacent frames was usually excellent (about 4 mm.). Nevertheless, their occurrence necessitates the observation that "pseudo infarcts" or inexplicable aberrations of motion do occur in about 1 per cent of healthy persons. The examinees' ages ranged from 13 to 36; most were about 22 years old and were college athletes!

[9] Dack, S.; Sussman, M.L., and Master, A.M.: Roentgenkymogram in Myocardial Infarction: Clinical and Electrocardiographic Correlation, Am. Heart J. 19:464-474 (April) 1940.

The location of the area of infarction does not always coincide with the area of abnormal motion seen in the kymogram. The infarct may be remote from the recorded segments but reveal itself by associated " splinting" of muscle contractions. Paradoxic movement does not require the presence of ventricular aneurysm: if one segment of the heart is immobile while the remainder of the ventricle contracts, that segment may show systolic expansion.

The probable age of the infarct cannot be determined from a single kymogram. The kymographic changes in cases of recent infarction are in general rather similar to those in cases of old infarction. A minority of cases of acute infarction will show (a) no immediate changes but changes developing after four to twelve weeks, or (b) immediate changes, with gradual improvement and return to normal after several months.[10]

In summary, the positive kymographic findings in myocardial infarction are (a) localized diminution or absence of pulsation, (b) systolic expansion or paradoxic pulsation, (c) partial systolic expansion or pronounced diastolic irregularities. Negative kymographic findings do not exclude the possibility of infarct but appear to occur in less than 30 per cent of cases. Positive roentgen findings are most frequent in cases of severe or extensive muscle damage.

INDICATIONS FOR ROENTGEN KYMOGRAPHY

The electrocardiograph is so far superior to the kymograph for the detection and confirmation of myocardial infarction that the question arises, "When should one employ roentgen kymography?" We believe that it is indicated when the clinical diagnosis is in doubt or the electrocardiographic findings are lacking or equivocal in a patient with symptoms of coronary disease or coronary insufficiency.[12] It may be useful in the prognosis of some atypical cases, since the degree of kymographic change or abnormality usually parallels the extent or severity of infarction. Furthermore, it has been shown that the kymogram is often more reliable in designating the severity of the infarct than is the electrocardiogram.[9] Therefore the kymogram has greater potential prognostic significance than the electrocardiogram.

RELIABILITY OF ROENTGENKYMOGRAPHIC DIAGNOSIS

In experienced hands, we believe that the method is reliable. Positive kymographic findings have been reported in as high as 91 per cent of a series of cases of proved myocardial infarction.[13] Sussman and others[10] reported positive findings in 75 per cent of 200 clinically definite cases of infarction. Others reported such findings in 71 per cent of cases.[14] In our own hands we have found positive findings in about 66 per cent of cases with clinically definite lesions. However, we have also encountered a few instances (we believe about 1 per cent of all cases examined) of inexplicably silent frames in healthy young persons. None of these could reasonably be attributed to localized infarction or adherent pericardial scar. Their explanation remains obscure, and their finding a reminder that no test is 100 per cent decisive. They may have been due to anomalous but physiologic pendulum or other movements.

CORRELATION OF KYMOGRAPHIC AND ELECTROCARDIOGRAPHIC FINDINGS

In this particular study roentgen kymograms were made in over 350 cases of various suspected or known cardiac disorders, ranging from mild functional disturbances to frank coronary disease; of these, 275 are available for review. For 249 of the patients satisfactory electrocardiographic tracings were made. To test the reliability of kymography it was decided to use the electrocardiogram as an accepted aid for the diagnosis of cardiac disorders and then to match the kymograms against that method. The majority of the electrocardiograms were made with a Cambridge "simplitol" instrument, standard limb leads and the 4 F being used. The interpretations were made by experienced cardiologists, most of them having been done by Dr. (then Lieut. Commander) Maurice Sokolow, who gave us advice and assistance.

For purposes of analysis, the actual reports as sent for the patient's charts were reviewed and classified as " positive," " negative" or " questionable." In the case of the electrocardiograms such conclusions as " left ventricular strain," " myocardial damage," and " coronary disease" were classified as positive; the phrase " tracing within normal limits" was recorded as negative; borderline interpretations were labeled questionable. Similarly, in the case of the roentgenologic reports, " myocardial abnormality" or " paradoxic motion" was classified as positive;

[14] Master, A.M.; Gubner, R.; Dack S., and Jaffe, H.L.: Form of Ventricular Contraction in Cardiac Infarction: Fluoroscopic Studies, Proc. Soc. Exper. Biol. & Med. 41:89-94 (May) 1939.

apparently normal reports as negative and indecisive reports as questionable. We realize that more specific designation of the electrocardiographic patterns might be desired by cardiologic readers, but space does not permit such excursion herein. The interpreters were experienced cardiologists and their conclusions were used as a base line.

The two methods correlated in 201 cases (80.5 per cent), and failed to do so in 48 (19.5 per cent). Analysis of the latter disclosed that failures were made in a "positive kymographic and negative electrocardiographic" fashion and vice versa fourteen times, thus leaving 34 cases in which there was no adequate explanation. However, in this group of 34 cases, it was found that 28 had questionable elements in the interpretation of the electrocardiographic tracing or the kymographic film (table 1).

TABLE 1.—*Correlation of Kymograms and Electrocardiograms in the Diagnosis of Myocardial Disease (249 Cases)**

Kymogram	Electrocardiogram	Cases	Percentage
Positive	Positive	28	11.3
Negative	Negative	146	58.4
Questionable	Questionable	27	10.8
Total Correlated		201	80.5
Kymogram	Electrocardiogram	Cases	Percentage
Negative	Positive	8	3.3
Positive	Negative	12	4.8
Positive	Questionable	3	1.3
Questionable	Positive	5	2.0
Questionable	Negative	8	3.3
Negative	Questionable	12	4.8
Total Failure of Correlation		48	19.5

*The kymograms were made within three to five days of the electrocardiograms in the vast majority of instances. The cases included miscellaneous types of cardiac disease or disorder, not exclusively infarctions. The designation of various electrocardiographic and roentgen patterns as positive or negative is explained in the text.

TABLE 2.—*Correlation of Kymograms and Electrocardiograms in Diagnosis of Myocardial Infarctions (58 Cases)*

Kymogram	Electrocardiogram	Cases
Positive	Positive	19
Negative	Negative	5
Questionable	Questionable	9
Correlation		33 = 56.8%
Kymogram	Electrocardiogram	Cases
Negative	Positive	4
Positive	Negative	10
Positive	Questionable	3
Questionable	Positive	3
Questionable	Negative	3
Negative	Questionable	2
Failure of Correlation		25 = 43.2%

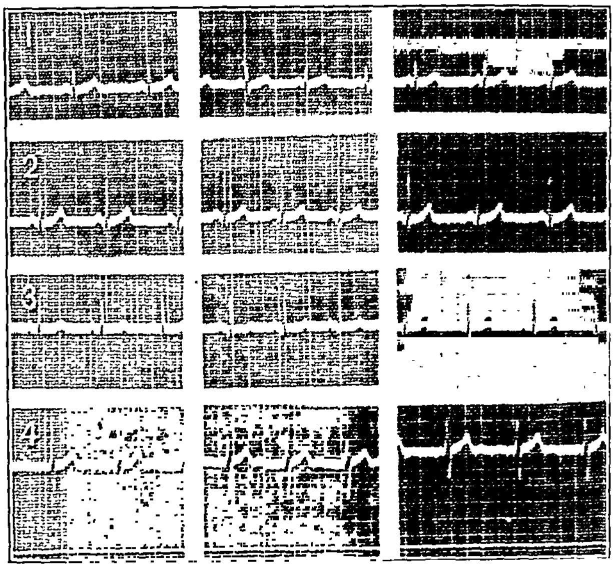

Fig. 4.—Example of negative electrocardiogram in myocardial infarction. Three sets of electrocardiograms made on different dates (from left to right, Dec. 30, 1944 and Jan. 1 and Jan. 3, 1945) were all reported by the cardiologist as within normal limits; normal series rhythm; rate 74 to 93; P-R 0.13 to 0.12; QRS 0.08 to 0.07 second. The roentgenkymogram (fig. 5) was indicative of severe myocardial abnormality. The clinical diagnosis was coronary occlusion with infarction.

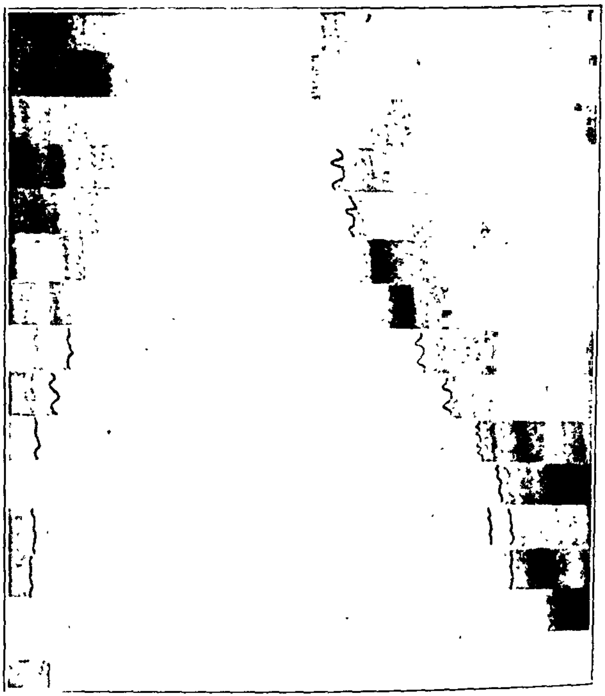

Fig. 5.—Posteroanterior kymogram of man aged 36. Note the poor amplitude of the waves over the entire left side of the heart and over the lower half of the right. These findings were also present in both the left anterior oblique and the right anterior oblique projections. Roentgen diagnosis was myocardial disease, severe, probably infarction. Clinically the patient had substernal pain and dyspnea, but his electrocardiogram was negative (fig. 4). He was allowed to go on leave. After he had sprinted to catch a train his attacks recurred. The electrocardiographic findings then showed changes indicative of myocardial disease. Final clinical diagnosis was coronary occlusion with infarction.

Therefore, the actual aid that either one of these tests might be to the other is greater than the figures suggest. In other words, when one of these tests was positive and the other questionable, one acted to confirm the other. Conversely, when one was negative and the other questionable, it was more likely that the negative result was correct. This might be expressed as an equation (K being used for kymograph and E for electrocardiogram):

E (or K) Positive + K (or E) Questionable = Probable infarct
E (or K) Negative + K (or E) Questionable = Probably no infarct

If this is conceded, we resolve 28 of the cases in which there was failure of correlation of the two methods. The other 20 cases cannot be adequately explained in the light of our present knowledge. However, even if there were no adequate explanation for these, it is evident that the over-all result would be an error of less than 10 per cent, which in clinical work must be regarded as indicating a relatively reliable method of examination.

KYMOGRAPHIC FINDINGS IN CASES WITH INFARCTION

In 58 cases with a clinical diagnosis of infarction positive or probable kymographic changes were noted in 47 (or 81 per cent). In 10 of these 58 cases the electrocardiogram was negative when the kymogram was positive. It was in this small group that the method proved of real diagnostic and sometimes of decisive value. We say " sometimes" because of the fact that although electrocardiograms were negative in all 10, the clinical history or associated findings were so clearcut as to be diagnostic in at least 5 of them.

REPORTS OF CASES

The following cases are illustrative of the findings noted in this group:

CASE 1.—A white man, aged 48, had a clinical diagnosis of coronary occlusion. The electrocardiogram was reported as questionable. Kymograms were positive for extensive myocardial abnormality, presumably infarction of the left ventricle. (Figs. 2 and 3). This patient, a physician, had precordial distress on effort for about four weeks and paroxysms of tachycardia. Roentgenoscopy disclosed a moderately enlarged heart, with localized bulging of the midportion of the left lateral border and systolic expansion (ventricular aneurysm). A subsequent electrocardiogram was reported as " intraventricular conduction defect with changes indicative of infarction." He died nine days after entry. Autopsy disclosed that the lateral wall of the left ventricle was soft and mushy, with adherent thrombus, secondary to old myocardial infarct.

CASE 2.—A white man, aged 36, had a clinical diagnosis of possible myocardial disease (substernal pain and dyspnea being the complaint on admission. Electrocardiograms were repeatedly negative (fig. 4). Kymograms were positive for myocardial abnormality (fig. 5). Repeat kymograms confirmed the presence of waves of poor amplitude, with one area of splintering and one area suggestive of parodoxic movement in the third frame above the left leaf of the diaphragm. On this basis, a roentgenkymographic diagnosis of myocardial infarct was made.

However, because of the slim clinical and negative electrocardiographic findings, the patient was allowed to go on convalescent leave and returned to his home in New York. While running to catch the train for his return trip, he suffered a severe stabbing pain in the anterior part of his chest which lasted for almost an hour; he had at least

Fig. 6.—Posteroanterior kymogram of man aged 65. Note the shallow or paradoxic pulsations over most of the left ventricular border due to myocardial infarction. The electrocardiogram was negative at time of this roentgenkymographic study. There was verification at autopsy three weeks later (old and recent left ventricular wall infarcts).

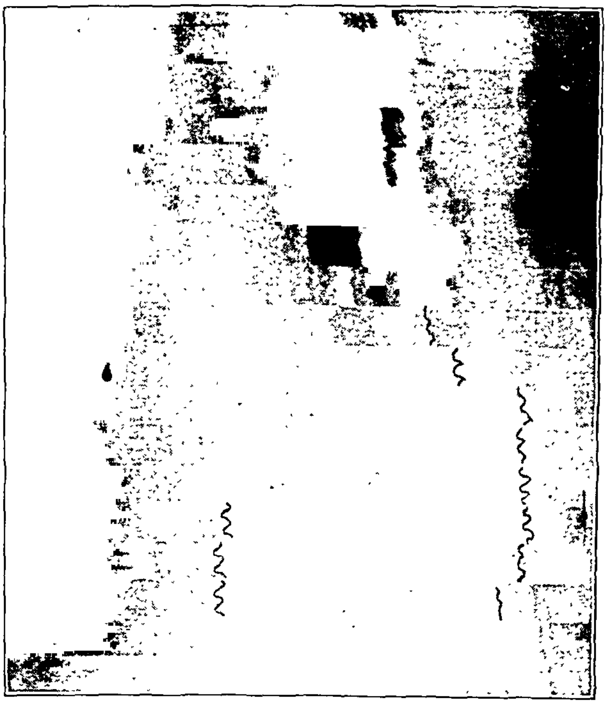

Fig. 7.—Left anterior oblique kymogram of same patient as in figure 6.

two similar attacks during the journey. Subsequent electrocardiograms showed progressive changes. The final clinical diagnosis was myocardial infarction.

CASE 3.--A white man, aged 65, with clinical diagnosis of arteriosclerotic heart disease had had recent attacks of nocturnal pain in the chest and dyspnea. Electrocardiograms showed evidence of "chronic ventricular strain." Kymograms were positive for myocardial damage (figs. 6 and 7). Subsequent electrocardiograms repeatedly showed evidence of "chronic coronary insufficiency, without evidence of recent infarction."

The patient was discharged home, but returned after some weeks with pulmonary edema. He died shortly thereafter. Autopsy revealed recent and old coronary thromboses and extensive infarction of the left ventricular wall.

CASE 4.--A white man, aged 48 had a clinical diagnosis of angina pectoris. Electrocardiograms were repeatedly negative. Kymograms were positive for severe myocardial disorder, presumably infarction (fig. 8). The clinical diagnosis was reconsidered following observation that the distress was epigastric in location, unrelieved by glyceryl trinitrate, amyl nitrite or medicinal doses of alcohol, but immediately relieved by sodium bicarbonate and eructation. Roentgen studies of the gallbladder and gastrointestinal tract gave negative results. He gradually resumed exercise, could walk on level ground without distress and after four weeks was anxious to return to his light duties as a training school supervisor. He felt so well that, in view of the negative electrocardiographic findings, the clinician doubted that he had any significant myocardial lesion.

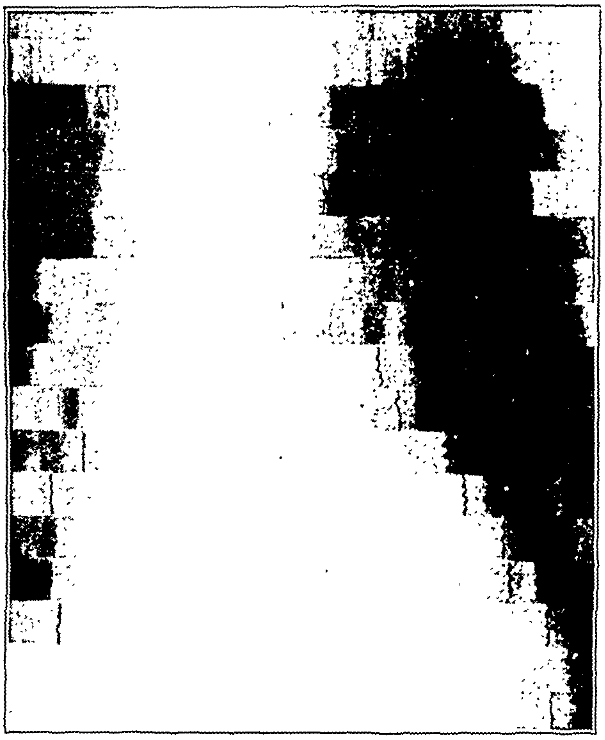

Fig. 8.—Posteroanterior kymogram of man aged 48. Note the poor amplitude of waves over most of the left ventricular border, with reversed pulsation in frames 3 to 5 above the left hemidiaphragm (infarction). The electrocardiogram was negative. The clinical history was questionable. Patient was released from hospital for ambulatory convalescence at home. Acute substernal pain developed within twenty-four hours of his departure from the hospital. Autopsy next day disclosed acute and recent infarction.

Repetition of the kymograms five weeks after entry confirmed the presence of "waves of poor amplitude over portion of the left ventricular margin, consistent with localized infarction." A repeat electrocardiogram next day showed some change, principally in the fourth precordial lead, which now revealed slight depression of the ST segment and inversion of the T wave. Until this second electrocardiogram became available, the only direct evidence of myocardial infarction was the kymographic. Indeed, the patient's second referral note to the radiologist read "Please repeat the kymographic study. The cardiac diagnosis hinges entirely on your findings."

The patient continued feeling well and was allowed to leave the hospital to subsist at his nearby home, pending completion of a discharge under the diagnosis of angina pectoris. On the evening after his departure he was awakened at 10 p. m. with severe epigastric pain; he took glyceryl trinitrate without relief and then sodium bicarbonate with some relief. He slept again until about 1 a. m., when he awoke with exquisite pain in the chest, went into shock, became pulseless and died in less than an hour.

Autopsy on the following day disclosed patchy coronary sclerosis, with thrombosis of the interventricular branch of the left coronary artery as its origin. There was extensive fresh infarction of the lower part of the interventricular septum and portion of the anterior wall of the left ventricle. There was older scarring of the posterior surfaces of the right ventricle near the apex.

SUMMARY AND CONCLUSIONS

The roentgen kymographic criteria suggestive or indicative of myocardial infarction are outlined. It is shown that roentgenkymography is a useful adjunct in the diagnosis of myocardial infarction, especially of "subacute" "healed" infarcts (particularly in cases with equivocal or negative electrocardiographic findings). It permits a permanent record of ventricular contractions. Ten cases are reported in which the kymographic findings led to a correct diagnosis of infarction, despite negative electrocardiographic or indefinite clinical findings. These constituted approximately 17 per cent of the cases of myocardial infarction studied in this series. The correlation of roentgenkymographic and electrocardiographic findings in the entire group of 249 cases with miscellaneous types of cardiac disorders was 80.5 per cent.

ABSTRACT OF DISCUSSION

DR. PHILIP J. HODES, Philadelphia: Drs. Garland and Thomas have reemphasized the importance of kymography in the diagnosis of myocardial infarction. They stressed the significance of paradoxic cardiac pulsations and splinting of the cardiac silhouette in this condition. They reminded us that negative kymograms do not exclude the presence of myocardial infarcts. Conversely, recognizing the pitfalls inherent in the method, the authors reviewed the false positive kymograms produced by normal vertical contractions of the heart near its apex as well as the abnormal contractions occasionally seen in systemic disease or cardiac diseases of other than vascular orgin. Whereas the authors did not discuss posterior cardiac infarcts specifically, I am sure that they appreciate the limited value of kymography in these lesions. This is due to the fact that the left ventricle, lying low on the left hemidiaphragm, is seen with difficulty in the lateral view, where it is obscured by the higher lying right hemidiaphragm and the liver, which makes it difficult to record changes in the posterior portion of the left ventricle kymographically. Much more easily found are the anterior, anterolateral and lateral lesions. No one can question the importance of kymography for the patients whose records have just been called to our attention. The authors were faced with a group of persons suspected of having cardiac disease but in whom the diagnosis was not established until Drs. Garland and Thomas submitted their kymographic data. There is evidence, however, that had four or more electrocardiographic precordial leads been used by the cardiologist instead of the one precordial 4 F lead utilized, the diagnosis might have been made in these patients by the cardiologist without kymography. All the more credit is due the authors, as well as kymography, because both were put to the test and met the challenge successfully. No discussion of this subject would be complete without reference to the electrokymograph recently discovered by the Chamberlain group of the Temple Medical School, which includes Dr. George Henny and Dr. Boone. It is hoped that their method of amplification and the other amplifying methods that stem from their original work will eventually make the diagnosis of myocardial infarction more easy and reliable.

DR. W. EDWARD CHAMBERLAIN, Philadelphia: I have recently had a pleasant surprise in that my expectations in regard to the electrokymograph have not been fulfilled in the direction that I expected. I had thought that I would be able to get along without roentgenkymography after the advent of electrokymography. After all, roentgenkymography is to electrokymography as big letters on a blackboard are to rather fine print. So it was with some surprise and some satisfaction, in view of the beautiful work done in roentgenkymography and the literature, added to today by Dr. Garland, that I find roentgenkymography is here to stay. I think that electrokymography will increase the value of roentgenkymography because it gives one many points on the heart boards. I am using roentgenkymography more than ever before. I should like to ask Dr. Garland if he would reduce the percentage of agreement to 70 per cent from the 80.5 per cent he gave, simply because I do not like to see in the 80.5 per cent of agreement the 10.5 per cent in which kymography was questionable. I would believe the real percentage would be 70 per cent, and that would be much closer to what we have obtained on myocardial infarction as we find it with the kymograph.

DR. L. HENRY GARLAND, San Francisco: In reply to Dr. Hodes' kind discussion, I cannot agree completely with him. Often one gets a positive kymograph because of "splinting." I do agree that infarction should not be excluded without multiple projections, and conversely that an attempt should be made to confirm kymographic findings with the electrocardiograph. In reply to Dr. Chamberlain's suggestion concerning reduction of the percentage agreement, I wish to point out that Dr. Thomas consulted Professor Weymouth of Stanford University and received his assurance that the figures given were valid and significant. Some of the cases which best illustrated the value of kymography were those with no clinical evidence of infarction, but with kymographic and autopsy proof of such. However, I do not wish to insist on verification at autopsy, since it is known that myocardial ischemia may result from coronary disease and sometimes give clinical and electrocardiographic evidence of infarction without postmortem demonstration of such.

ACTINOMYCOSIS OF THE CENTRAL NERVOUS SYSTEM

A Case of Meningitis with Recovery

J. ROBERT JACOBSON, M.D.
and
RALPH B. CLOWARD, M.D.
Honolulu, Hawaii

The invasion of the central nervous system by the mold Actinomyces is rare. Ford[1] stated in 1937, "There are now 40 cases on record in which the nervous system has been invaded by the ray fungus. All reported cases have been fatal; no treatment is of any value." Friedman and Levy[2] after an extensive review of the literature found that 108 cases had been reported. Two more cases of actinomycotic meningitis have been added to the literature since this report[3] (1941). When the disease attacks the central nervous system, it is universally considered to be 100 per cent fatal. No case of recovery has as yet been reported.

Actinomycosis occurs in the central nervous system usually as a direct extension of an infection about the head; i. e., the upper jaw, the sphenoid sinuses or the mastoid. The nasopharynx has been suspected as a possible source of the original infection.

The organisms, however, can be transmitted through the blood stream. "Primary" infections in the brain are those in which no other lesion can be found outside the central nervous system. Twenty-three such cases were found by Friedman and Levy. Zeitlin and Lichtenstein[4] (1937) reported a case of brain abscess due to actinomycosis. They found a microscopic focus of infection in the body which they thought was primary. Most authors believe that the "primary" cases are those in which the original focus has either healed or has not been discovered.

LITERATURE

The literature on actinomycosis of the central nervous system can be divided into the reports published prior to the advent of chemotherapy (1937) and those appearing since. The most complete report by Friedman and Levy[2] (1936) reviews the entire medical literature on the subject up to that time. One hundred and eight cases were found, and 90 of these are briefly summarized by the authors. The average case shows thick pus in the spinal fluid with high cell counts, predominantly polymorphonuclear leukocytes; sugar is absent. The temperatures range from 101 to 102 F. The patients do not appear as toxic as would be expected from the abnormalities noted in the spinal fluid. There is usually paralysis of several cranial nerves. The white blood cell count ranges from 17,000 to 25,000. Sudden, unexpected death in a patient who seems not too acutely ill is characteristic of the disease.

Clinical Director of the Territorial Hospital (for the Mentally Ill), Kaneohe, Oahu, Territory of Hawaii (Dr. Jacobson) and Neurosurgeon, The Queen's Hospital, Honolulu, Territory of Hawaii; Consultant, Neurology and Neurosurgery, The Territorial Hospital, Kaneohe, Oahu, Territory of Hawaii (Dr. Cloward).

Friedman and Levy concluded their article by stating, "There is no treatment for the disease; all cases are fatal."

The following year (1937) the first case of systemic actinomycosis to be treated with the sulfonamide drugs was reported. Poulton[5] described a patient with actinomycosis of the abdominal wall who recovered with the use of sulfanilamide after all other methods of treatment had failed. A similar case was recorded by Miller and Fell[6] in 1939 Sudler and Johnson[7] reported 2 cases of cervicofacial involvement cured with sulfanilamide. Other cures of abdominal actinomycosis with the sulfonamide compounds were reported by Ogilvie[8] (1940) and Dorling and Eckhoff[9] (1940) The latter authors treated 5 patients with sulfanilamide and sulfapyradine with 4 recoveries and 1 death. They recommended giving two or three "courses" of treatment, each course consisting of 45 Gm. of sulfonamide drug, lasting one week, with a one week rest period between. They stressed the frequency of recurrence of the disease and the danger of regarding a remission as a cure.

Dobson and Cutting[10] (1945) reported the use of penicillin as well as sulfonamide compounds in treating 16 patients with actinomycosis. The disease was pulmonary in 3 patients, abdominal in 2 and cervicofacial in 11. In 7 of these patients the disease was considered arrested; 7 recovered and 2 died after intensive sulfadiazine and penicillin therapy. Penicillin was used alone and in combination with sulfadiazine. The authors concluded that both drugs are highly effective in the treatment of actinomycotic infection.

A recent report by Lamb, Lane and Jones[11] (1947) recognizes the value of the chemotherapeutic agents, but these authors were not as enthusiastic about the specific value of these agents as stressed by previous authors.

The last report of actinomycosis of the central nervous system was recorded by Eckhoff.[3] His 2 patients with basal meningitis both died after many months of illness.

It is the purpose of this communication to record the first case, as far as we are able to determine, of verified actinomycotic meningitis in which complete recovery followed adequate treatment with chemotherapy

REPORT OF CASE

A. B., an unmarried Japanese woman aged 28, was committed to the Territorial Hospital on March 22, 1947 with a diagnosis of manic depressive psychosis, manic type, "with atypical features of hysteria and at times schizophrenia."

The psychiatric history suggested a psychopathic heredity. One maternal aunt and one cousin had committed suicide. The patient had been raised in an environment of sexual promiscuity with the practice of prostitution by her mother and sister to a limited degree. The patient, at the age of 14, had worked in a teahouse where she was frequently subjected to the advances of men, but she insisted that she had repulsed them. The symptoms of her present mental illness had begun eighteen months before, when she became deeply concerned over her approaching marriage. In December 1946 she became overtalkative, distractible, sleepless and hyperactive. On admission to the Mental Hygiene Clinic of The Queen's Hospital for treatment, she was belligerent, resistive, combative and hyperactive. After ten electric shock treatments she improved, and treatment was continued in the outpatient department. In March 1947 she again became disturbed, and after showing no improvement from the treatment she was committed to the institution.

On admission to the Territorial Hospital, she exhibited much the same hyperactive, restless, resistive behavior with marked hysterical symptoms. She had numerous somatic complaints of headache, backache, pains in the neck and astasia abasia. She would fling herself to the floor saying that she could not stand or walk.

The physical examination revealed no significant abnormality. The only positive finding was a palpable mass about 1 cm. in diameter at the anterior border of the sternomastoid muscle at its midpoint. It was thought to be a lymph node. The patient stated that two years before this "lump" had appeared in her neck. It had been considerably larger and rather painful She had had pains in the neck and occiput for which several physicians had been consulted, none of whom had considered the "lump" as being pathologic. She had been told that nothing was wrong. It could not be distinguished from a nonspecific lymphoadenopathy. (In the light of later developments, the possibility that this lesion represented the primary focus of the actinomycotic infection must be considered.) No biopsy of the node was made.

The neurologic examination was entirely normal. The fundus showed flat optic disks. No abnormalities of the lungs were found in the roentgenograms of the chest. Blood cell count and the urine were likewise normal. The examination of the spinal fluid on admission showed no cells, a negative Wassermann reaction and flat mastic curve with a total protein of 19 mg. per hundred cubic centimeters.

While in the hospital, except for the psychotic behavior which improved somewhat, the patient was physically well until May 8, 1947, when a temperature of 101 F. developed. She began to complain of backache and pains in her neck, more bitterly than her previous hysterical complaints. Examination disclosed positive Kernig and Brudzinski signs with tenderness and resistance to passive movement of the cervical muscles. The clinical diagnosis of meningitis was verified by lumbar puncture. The abnormalities noted in the spinal fluid were most surprising in view of the mild clinical symptoms. The spinal fluid was cloudy and contained 4,790 cells per cubic millimeter, 83 per cent of which were polymorphonuclear leukocytes. There was no sugar and a positive globulin reaction. The white blood cell count was 25,050. No organisms could be seen on direct smear of the spinal fluid.

She was immediately placed on penicillin, given intramuscularly, intravenously and intrathecally, and was given sulfadiazine by mouth. During the first week she received 45 Gm. of sulfadiazine and 2,500,000 units of penicillin—50,000 units, well diluted, were given daily intrathecally. Routine bacteriologic studies of the spinal fluid in the hospital laboratory had failed to disclose the organism, and a tentative diagnosis of tuberculous meningitis was considered. However, because of the high cell count, mostly polymorphonuclear leukocytes, further bacteriologic examinations were indicated. Accordingly, the spinal fluid was sent to the bacteriologic laboratory of the Territorial Board of Health, under the direction of Dr. Richard K. C. Lee, for further study.

The patient's clinical condition showed no improvement the first week. Regardless of chemotherapy the spinal fluid cell count rose from 4,000 to 7,000. Streptomycin was then added to the treatment. It was administered both intramuscularly and intrathecally. A total of 26 Gm. was given in six days. At one time all three chemotherapeutic agents were being administered simultaneously.

A bacteriologic report that the spinal fluid contained Actinomyces was received on May 15, 1947 The neurologic examination on that day disclosed 4 to 5 D of papilledema bilaterally, and weakness of both lateral rectus muscles Other cranial nerves were normal. The neck was stiff There was generalized muscular weakness and suggestive localized weakness of the left extremities. All tendon reflexes were absent; there were no pathologic reflexes. The patient's temperature remained between 101 and 104 F. daily. She was conscious and cooperative but listless and appeared toxic The possibility of a brain abscess was suggested. A ventriculogram was done on May 16, 1947.

Through a single burr hole in the right frontal bone, the anterior horn of the ventricle was tapped with a brain needle, replaced by a no. 12 rubber catheter, which was sutured to the scalp and left in place. The brain was tight and bulged markedly through the small dural opening The ventricular fluid, released under considerable pressure, was cloudy and contained 1,300 cells. Twenty cubic centimeters of fluid was removed from the ventricular system and replaced with oxygen The lateral ventricles as seen in the roentgenogram were small, equal in size and shape and situated in the midline. The roentgen diagnosis was cerebral edema without brain abscess

The ventricular catheter was opened and the ventricular fluid allowed to drain through it continuously for twelve days, relieving the intracranial pressure. Large doses of penicillin were continued intravenously during the first six days and replaced by sulfadiazine the second six days. The spinal fluid began to show *improvement after the ventricular drainage* was established. On May 22 there were 1,500 cells The sugar appeared for the first time with 36 mg. per hundred cubic centimeters, and the cultures, which up to this time had all contained Actinomyces, were sterile.

The patient improved steadily; the septic temperature curve, which had remained above 101 F. for five weeks, gradually returned to normal. Sulfadiazine alone was continued the last three weeks, 45 Gm. being given weekly.

On June 5 she was *considered clinically* well. The spinal fluid was clear, the cell count 33, the sugar 92 mg. per hundred cubic centimeters, the total protein 35 mg. per hundred cubic centimeters and the mastic curve 34555. She was discharged from the hospital completely recovered from her mental illness as well as the meningitis and has remained well to the present time (Nov. 1, 1947).

COMMENT

The manner in which the chemotherapy was administered in this patient from the onset and throughout her illness may be criticized but, in the light of our present knowledge that we were treating a 100 per cent fatal disease, the intensive chemotherapy appears justified. Intensive treatment with sulfadiazine, penicillin and streptomycin was administered singly and in combinations, by every possible route. One cannot, therefore, state which drug was largely responsible for effecting the cure. Perhaps, the combination of two or more may have been more effective than any one alone. It would seem that the streptomycin had therapeutic value, because clinically the patient began to improve and the spinal fluid cell count began to drop after the streptomycin was started. The continuous ventricular drainage was started at about the same time. It is difficult to evaluate the efficacy of this procedure as far as the infection, per se, is concerned. It did relieve the intracranial pressure. The papilledema subsided rapidly after the ventricular drainage.

The relation of the mental illness to the infection must be considered. The mental symptoms began one and one-half years before, coincident with the appearance of the "lump" in her neck. Whether this represented a "metastasis" to the central nervous system is entirely speculative. A dormant abscess of the frontal lobe subsequently rupturing into the subarachnoid space might explain the relationship between the psychosis and the meningitis, but this too is conjectural. The patient's psychosis, however, completely cleared up as she recovered from the meningitis.

BACTERIOLOGIC REPORT

Since actinomycosis of the central nervous system is rarely diagnosed during life, it is appropriate that the complete bacteriological examination of this case be included. The following report signed by Dr. Richard K. C. Lee, Assistant Health Executive of the Board of Health, Territory of Hawaii, is given in its entirety.

The appearance of these spinal fluids was consistently the same, mainly cloudy with pieces of fibrous material resembling a pellicle. A wet preparation of a portion of the pellicle, examined under the microscope, revealed a few red blood cells and a large number of white blood cells, predominantly the polymorphonuclear type in each instance. Yeastlike forms were absent. Gram's and acid-fast stains of the centrifuged specimens failed to show any bacteria.

In all the specimens the same procedure of culture technic was followed. The sediment was planted on the following mediums: Petragnani's, chocolate agar incubated at 37 C. in approximately 10 per cent carbon dioxide atmosphere and sodium thioglycollate. The results obtained by culture media are as follows: 1. Blood agar plate (first and second specimens only: No growth was present after a period of one week. *The plates were discarded.* 2. *Chocolate agar: Small chalky* colonies appeared after seventy-two hours' incubation, appearing as dry looking and wrinkled with raised rough centers and crose-like edges. Stained slides of the growth showed coccic and diphtheroid-like forms which were gram positive and acid fast. Microscopic examination of a single colony by the wet preparation method showed spore-bearing myceliums seemingly radiating from a center. 3. Sodium thioglycollate: Tiny individual white colonies with pink centers suspended in the culture *medium were observed microscopically after ninety-six hours.* The gram-positive and acid-fast stains and wet preparation of the growth gave identical results as that on chocolate agar. Colonies were picked and subcultured to Sabouraud's medium. After forty-eight hours, small, rough, chalky dry colonies were observed which turned pink after a period of six days.

A culture of the fungus on Sabouraud's agar was sent to Dr. C. W. Emmons, Principal Mycologist, Division of Infectious Diseases, National Institute of Health, Bethesda, Md., for *identification. The fungus was identified by Dr. C. W. Emmons* as a typical culture of Nocardia asteroides, an acid-fast actinomycete.

SUMMARY AND CONCLUSION

This is the first report of a verified case of actinomycosis of the central nervous system, with recovery.

The advent of the sulfonamide drugs and penicillin have greatly modified the treatment of systemic actinomycosis. Recent literature has stressed the specific value of these drugs in actinomycotic infections.

This is the first case of actinomycosis of the central nervous system in which adequate chemotherapy has been given. It is our conclusion that intensive treatment with sulfadiazine, penicillin and streptomycin accounts for the good clinical results.

Streptomycin Treatment of Bubonic Plague.—Streptomycin treatment of three very severe cases of plague not responding to sulphonamides resulted in speedy recovery. A fourth severe case was not treated with streptomycin, and the patient died on the eighth day of his illness. Whereas the effect of streptomycin on the general condition of the patients was remarkably good, the buboes appeared to be uninfluenced if treated late. This was true also in respect of the sulphonamides, and in most cases incision and drainage were necessary to bring about resolution.——Haddad, C., M.D., and Valero, A., M.B., *British Medical Journal*, May 29, 1948.

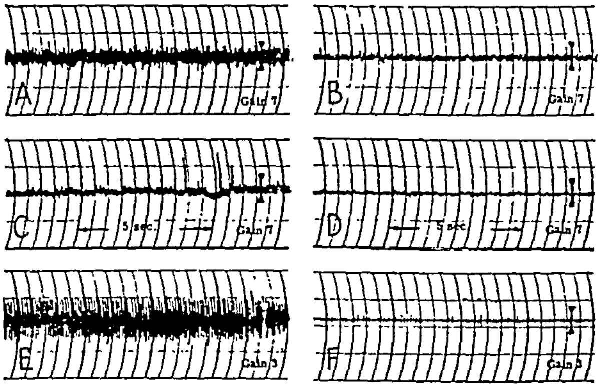
ORAL "MYANESIN" IN TREATMENT OF SPASTIC AND HYPERKINETIC DISORDERS

F. M. BERGER, M.D. and R. P. SCHWARTZ, M.D.
Rochester, N. Y.

The interesting pharmacologic properties of "myanesin" (3-ortho-toloxy-1,2-propanediol), such as its power to relax spasticity and rigidity, its action to restore deranged reciprocal innervation and its inhibiting effect on certain release symptoms, suggested that this drug may be useful in the production of muscular relaxation during anesthesia and for the treatment of certain spastic and hyperkinetic disorders.[1] "Myanesin" has since been widely used for muscle relaxation during anesthesia in Great Britain,[2] and it was recently reported that 10,000 patients received intravenous injections of this agent.[3]

The value of "myanesin" in the treatment of spastic and hyperkinetic disorders has not been examined as extensively. Stephen and Chandy[4] obtained short-lived beneficial effects on certain diseases of the extrapyramidal nervous system on intravenous administration of a 10 per cent solution of the drug. They also observed localized thrombophlebitis and transient hemoglobinuria following administration. These side effects were due to the solvents used in the preparation of concentrated solutions of "myanesin". Schlesinger and associates[5] observed that the use of 2 per cent solutions of "myanesin" caused neither phlebitis nor hemoglobinuria on intravenous administration; it ameliorated involuntary movements, rigidity, spasticity and tremor. The drug was, however, of limited clinical value because of its evanescent action and the alleged ineffectiveness after oral administration.[6] The purpose of this report is to draw attention to the fact that "myanesin" is well absorbed after oral administration,[1 a c] and to outline briefly the satisfying results obtainable in previously intractable conditions.

The drug was administered as 3.3 per cent (weight in volume) solution in 20 per cent (volume in volume) aqueous propylene glycol, with syrup of cherry 20 per cent (volume in volume to improve the taste of the mixture. The usual single dose was 30 cc. of the mixture equal to 1 Gm. of "myanesin." Children received proportionally smaller doses. To obtain objective and permanent evidence of the effect of the drug electromyographic records[7] were taken prior to administration of the drug. "Myanesin" was then administered without disturbing the leads and muscular activity recorded thirty to sixty minutes after administration of the drug. The disappearance or diminution of the abnormal muscular discharges in the electromyograms could be observed as soon as five to twenty minutes after administration of the drug (the figure). These changes were as a rule accompanied by other signs and symptoms, such as decrease of spasticity, increase of range of motion, amelioration of involuntary movements and relief of pain.



Electromyographic recordings before and after administration of "myanesin." I = 4,000 microvolts. *A, B, C,* and *D,* I = 140 microvolts; residual paralysis of apoplexy. *A* and *B,* leads from biceps brachii and rectus femoris respectively before administration of drug. *C* and *D,* same muscles fifteen minutes after oral administration of 1 Gm. "myanesin." *E* and *F,* parkinsonism. *F,* I = 1,400 microvolts; twenty minutes after administration of 1 Gm. "myanesin" orally.

The rapid absorption of "myanesin" from the stomach could be demonstrated by the presence of metabolic products of "myanesin" in the urine as soon as fifteen minutes after oral administration of the drug. The metabolic product gave a cherry red color on treatment of the urine with Ehrlich's diazo reagent. "Myanesin" itself did not give this reaction. Those workers who found the drug ineffective on oral administration presumably administered it in tablet form. The advantages of the oral administration of "myanesin" in the form of capsules or tablets are clearly evident. Initial experience suggests that tablets and capsules may be effective in certain cases.

Hemiplegic patients whose paralysis has been stationary for four to seven years showed a striking recovery of some of the voluntary movements of the paralyzed limbs ten to twenty minutes after administration of the drug. The maximum benefit was usually obtained after two

to three days of medication and could be maintained by giving 1 Gm. doses in the mixture three to five times daily. These observations show that loss of function in spastic paralysis is not necessarily or exclusively due to the destruction of motor pathways. It is possible that loss of movement in residual paralysis of apoplexy and spastic paralysis in general may be primarily due to the splinting action of spasticity. Spasticity is caused by an exaggeration of the stretch reflexes. The power of "myanesin" to bring about a return of function in spastic paralysis is due to its property of reducing exaggerated reflexes to normal without affecting the normal reflexes.[1c] In this way spasticity may be reduced without abolition of voluntary power.

Remarkable results were also obtained in certain cases of cerebral diplegia. The drug appeared effective in spastic, athetoid and choreiform types of the disease. In spastic diplegia the drug, in the doses given, caused but little diminution of spasticity as judged by the increased tendon jerks and clonus. Manipulation of the spastic limbs was, however, easier, and the physical performance of the patients improved. They were able to walk more quickly and for longer periods of time than before administration of the drug. The choreiform jerking movements were ameliorated to a somewhat greater extent than the slower athetoid movements. Some of these patients had lesions which were particularly sensitive to the drug. The athetoid movement and incoordination of a woman, 21 years of age, were almost completely controlled by a single 0.5 Gm. dose, but other patients derived less benefit from larger doses repeated several times daily. One patient (a woman of 22 years) while receiving "myanesin" (1 Gm. thrice daily) showed signs of decerebrate rigidity, which subsided again after discontinuance of the drug. The administration of smaller doses (1 Gm. once daily) ameliorated athetosis and did not cause side effects. The favorable effect of "myanesin" in diplegia is due to the depressant action of the drug on the nuclei of the brain stem and to its power to reestablish disturbed reciprocal innervation,[1c] which also plays an important part in the clinical picture of the disease. The amount of benefit derived will also depend on the exact localization of the cerebral lesion.

In Parkinson's syndrome the oral administration of "myanesin" reduced tremor and rigidity. The effect of the drug on oral administration was not as spectacular as that observed after parenteral administration, but it was of longer duration and did not cause side effects. The best results were obtained if "myanesin" was given in addition to the usual drugs of the atropine class. Certain patients derived only little benefit from the medication. This may have been due to too low a dosage, incomplete absorption or insensitivity of the pathologic mechanism to the drug.

The oral administration of "myanesin" also proved effective in various conditions causing muscular spasm, such as arthritis of the cervical part of the spine (fifth and sixth cervical vertebrae), subacromial bursitis, pain low in the back, osteoarthritis of the hip joint and similar conditions. "Myanesin" frequently relieved both spasm and pain due to spasm. Sometimes the action was transient and of short duration, and sometimes it was prolonged indefinitely. In the latter case this effect was thought to be due to an interruption of a pain-spasm vicious circle. "Myanesin" did not have any central analgesic action of the type possessed by morphine or meperidine hydrochloride, but had antipyretic properties of a similar or greater order than the salicylates. The effect of the drug in acute rheumatic fever would be of interest. "Myanesin" was ineffective in contracture due to ischemia, multiple sclerosis and thromboangiitis obliterans.

The oral administration of "myanesin" rarely caused side effects. Blood pressure, heart rate and respiration were not affected. Nystagmus, diplopia, mild muscular incoordination and other symptoms sometimes appearing after intravenous injection were not observed after oral administration. Only 1 out of the 59 patients treated thus far complained of anorexia. Nausea or vomiting were not complained of. Several patients experienced a transient feeling of lassitude for ten to twenty minutes after administration. This lassitude was not, however, great enough to prevent them from carrying out their usual duties. Samples of blood were frequently examined for hemoglobinemia with negative results. The results of the van den Bergh test were always within normal limits. The urine remained free from protein and blood in all cases, but always showed a positive reaction to the Ehrlich diazo test. The intensity of the color obtained with the urine was proportional to the amount of "myanesin" taken. Certain patients have now been on continuous medication for five weeks without showing side effects. Patients receiving the drug should, however, be watched closely, as the chronic effects of the drug on human beings are still unknown.

The benefit obtainable with oral administration of "myanesin" in spastic and hyperkinetic disorders is much greater than that obtained with curare, erythroidine, neostigmine or any other known remedy. But, there is a need for other drugs possessing a still stronger spasticity-releasing action. This preliminary communication is presented in the hope that it will make the life of those who cannot move as they wish more tolerable and stimulate interest in research designed to increase the understanding and essential resources for control of abnormal functions of the central nervous system.

CONCLUSIONS

The ortho tolyl ether of glycerol called "myanesin" has a relaxant effect on muscle slight delayed emptying. Patient 4 had a four year history of recurring, left-sided, renal pain. There was no infection. An oblique roentgenogram demonstrated a ureter coming off posteriorly. The patient did not have enough discomfort to desire surgical treatment. Patient 5 had bilateral infection, but drained well. The only symptom had been cystitis. Surgical treatment was not advised.

Of the nephropexies, I had one satisfactory result, and that was in a man who had bilateral ptosis and dilatation. An exploratory operation had been done for supposed intestinal obstruction, and the patient was found to have a large dilatation of the right renal pelvis, which was drained; drainage persisted as from a urinary fistula. On exploration an anomalous vessel was removed before nephropexy, which has resulted in a satisfactory course over a period of two years.

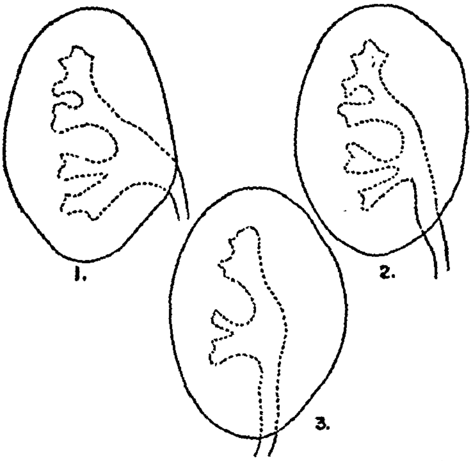

Fig. 1.— Variations as they appear in pyelograms.

The other patients with nephropexy have been worrying along with periodic spells of discomfort not disturbing enough to cause them to wish further surgical procedures. All of the patients with nephrectomy have done well except one who was diabetic. She had nephrectomy for recurring renal infection with dilatation on the right. It was felt that the removal of the infected kidney would prove helpful in her diabetic course. This has not proved to be true, and she not only had severe diabetes, but hypertension with varying periods of renal insufficiency, and incompletely emptying neurogenic bladder and infection of the remaining kidney.

The 2 patients whose lower pole was removed have done well.

COMMENT

Pathogenesis — Of this type of mechanism of development of renal pelvis is not too clear. Without going into too much detail and discussion, it is my impression that the location of the pelvis in the posterior aspect of the kidney is a result of the location of the initial fusion between the ureteral bud and the meta- os rather than rotation anomalies. My reason for feeling rather strongly that this is so is the fact that the kidney itself is usually flat and in the prone position and lies on the posterior abdominal wall like any normal kidney. Unless a lateral or oblique roentgeongram is taken, it may be impossible to determine whether the pelvis is anterior or posterior.

I have asked Charles G. Stockard, assistant pathologist at Doctors Hospital, to look for this type of kidney at the autopsy table. He has informed me that he has examined approximately 100 kidneys at autopsy and so far has failed to find this type of pelvis.

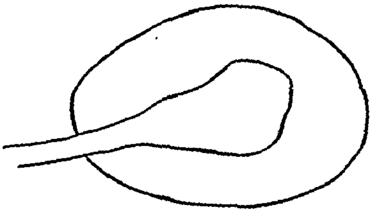

Fig. 2.— Posterior view of kidney.

Figure 1 is a conglomerate drawing of the variations in the pyelograms as they appear on the films. It is impressive to me that they do not appear more abnormal. Number 3, in this figure, is the most suggestive with respect to contour of the pyelograms and the relation of the ureter to the soft tissue outline of the kidney.

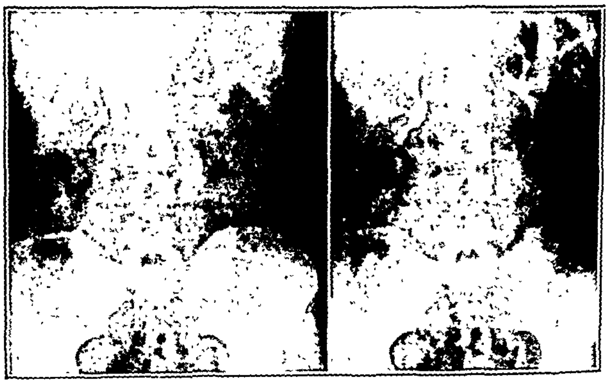

Fig. 3.— Showing gun barrel effect.

Figure 2 is a drawing of the pelvis of the posterior aspect of the kidney in a case in which the condition is pronounced.

The diagnosis of the posteriorly placed renal pelvis is suggested urographically by the gun barrel effect as shown in figure 3, and by the location of the ureter lateral to the medial pelvic border as suggested in figure 4.

Oblique rays may be of considerable value, as demonstrated in figure 5.

In only a few cases did roentgenograms suggest the presence of the posteriorly placed pelvis.

As one sees more of these cases, it is possible to suspect the presence of posteriorly located pelvis just by the appearance of the urogram rather than by any description that one may give of it. The removal of the lower pole or the removal of an anomalous vessel should be the procedure employed when it seems likely that such procedure has a reasonable chance to have a satisfactory result. Figures 6 and 7 illustrate resection of the lower pole.

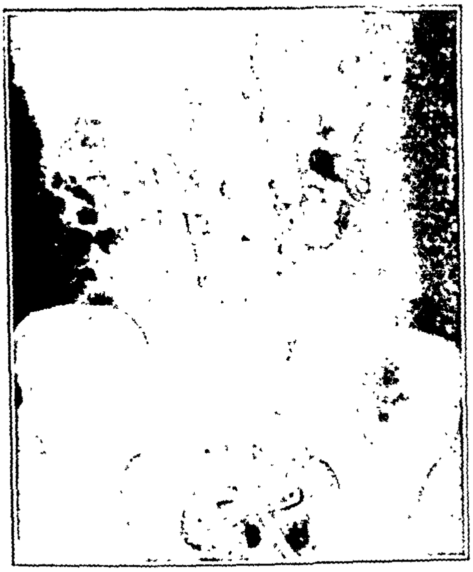

Fig.4.— The ureter seems to be lateral to the medial pelvic border.

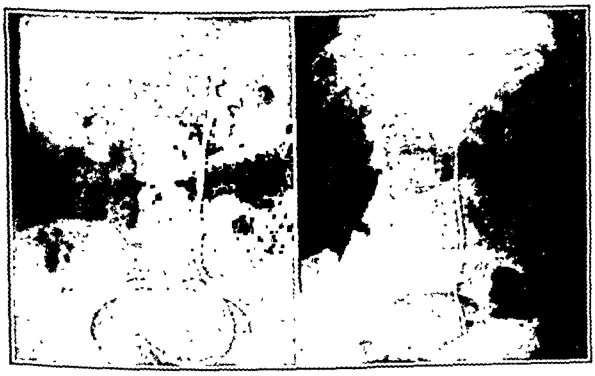

Fig.5.— Pyelogram on the left is anteroposterior. The pyelogram on the right is an oblique view and demonstrates the posterior location of the ureter.

Whenever the arrangement of the vascular pedicle is such that resection cannot be carried out, or an anomalous vessel removed to relieve obstruction satisfactorily, nephrectomy is the best procedure. Small caliber of the ureter is an indication for nephrectomy, for there is no procedure that I know of that can alter the caliber of the ureter in its entirety. This experience with these cases has been most interesting, and the most striking aspect of it is that in every instance when ptosis of the kidney was accompanied by symptoms that were sufficiently severe to demand surgical intervention, a posteriorly placed renal pelvis was always found to be present. As time goes on it may be possible in a larger proportion of cases to fashion the lower pole of the kidney in such a way that the ureter cannot be interfered with by an overhanging mass of renal tissue.

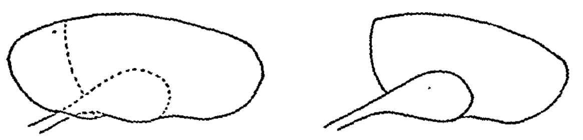

Fig.6.— Resection of the lower pole, lateral view.

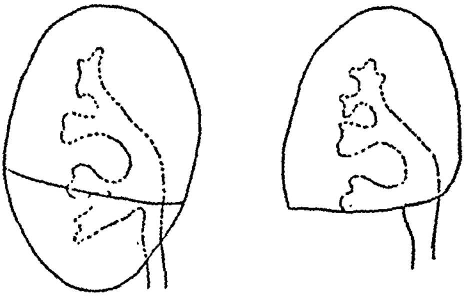

Fig.7.— Resection of the lower pole, front view.

CONCLUSION

The presence of a posteriorly located renal pelvis is an important factor in producing symptoms that are severe enough to indicate surgical procedures in many patients who have ptosis of the kidney.

URETEROPELVIC OBSTRUCTIONS: SYMPTOMS AND TREATMENT

Report of Seventy Cases, Sixty-Two Operations

ROY B. HENLINE, M.D.,
and
CECIL J. HAWES, M.D.,
New York

Often the sole manifestation of an obstructive renal syndrome may be a digestive upset with no urinary symptoms. The common nerve supply of the kidneys and the intestinal tract is well understood, and any renal irritation frequently results in indigestion, flatulence and nausea, yet this fact is often overlooked, particularly in the absence of symptoms attracting attention to the kidney. Also, it is too frequently stated that, since the urine is normal, the kidneys cannot be considered as the possible cause of gastrointestinal symptoms. Many serious urologic lesions may exist even when the urine is normal.

The principles of the treatment for partial obstruction at the ureteropelvic junction are being more universally recognized by urologists. Successful repair of this deformity, with resultant conservation of renal tissue, is often accomplished, and yet the general medical profession is not wholly aware of these improvements. Formerly, kidneys with

---

Read before the Section on Urology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

ureteropelvic obstruction and varying degrees of hydronephrosis were removed, mainly because the results from plastic surgery were so frequently unsuccessful that, subsequently, the kidney had to be sacrificed. Although each patient must be considered individually, our aim should be to preserve functioning renal tissue in most of these cases. Greater success has been accomplished by a better understanding of the principles involved in the surgical repair, together with the use of the new antiseptics and antibiotics.

A preliminary report by Henline and Menning[1] in 1943 stated:

> The successful treatment of hydronephrosis due to ureteropelvic obstruction postulates, first, a knowledge of the etiological factor or factors involved and their proper recognition and evaluation at operation. It is all too familiar that merely severing aberrant vessels in certain cases results in temporary or no improvement. Second, a surgical procedure must be applied which is best adapted to the correction of a given deformity. The technique should restore a well-draining pelvi-ureteral outlet. Third, complete plastic repair requires prolonged nephrostomy drainage and splinting of the area of repair. Where this is neglected, secondary contracture and distortion at the site of the repair will vitiate the initial surgical correction, no matter how meticulous the technique.

Our success in these earlier cases indicates that satisfactory results in our hands depends, to a large extent, on the fulfilment of certain fundamental principles. First, the diagnosis should be made by a ten minute delayed roentgenogram following retrograde pyelography. The site of the obstruction at the ureteropelvic junction is seen, and the delay in the emptying of the kidney pelvis is apparent (fig. 1). Second, the exact cause of such obstruction must be sought and corrected at the time of operation Intrinsic stenosis at the ureteropelvic junction is the most common cause. Even if aberrant vessels and bands are also present, their separation may relieve only part of the cause of the obstruction. In this case, the intrinsic stenosis must also be remedied. Third, the deformity must be adequately corrected and, as a rule, the narrow ureteropelvic junction must be incised longitudinally. We have preferred the Foley Y plasty in most instances. Fourth, the third principle is likely to fail unless nephrostomy drainage to divert the urine is established and a soft rubber catheter is inserted as a splint down the ureter. We have permitted both the nephrostomy tube and the splinting catheter to remain in place for six weeks to allow for complete healing of the repaired ureteropelvic junction. Fifth, resection of a portion of the enlarged pelvis and careful suture of the areas to be approximated are desirable. Careful suturing may be less important than the other principles in the repair of this deformity.

Once the diagnosis of ureteropelvic obstruction has been made, the choice of treatment must be considered. Local treatment, such as dilating the narrowed area with catheters, bougies or bulbs, is notoriously unsuccessful. While it is true that symptoms may be relieved for varying periods by passing a catheter through the constricted area, the permanent benefits have not been encouraging in our hands. The temporary establishment of drainage by a catheter will usually relieve the renal colic, but symptoms will recur in most instances. The narrowing of the ureter persists, and continued back pressure in the pelvis will further damage the kidney. In some instances it is advisable to leave the patient alone and subject him to reexamination to evaluate the progress of the obstruction. However, in most instances, surgical intervention is necessary to relieve the obstruction and prevent continued renal damage.

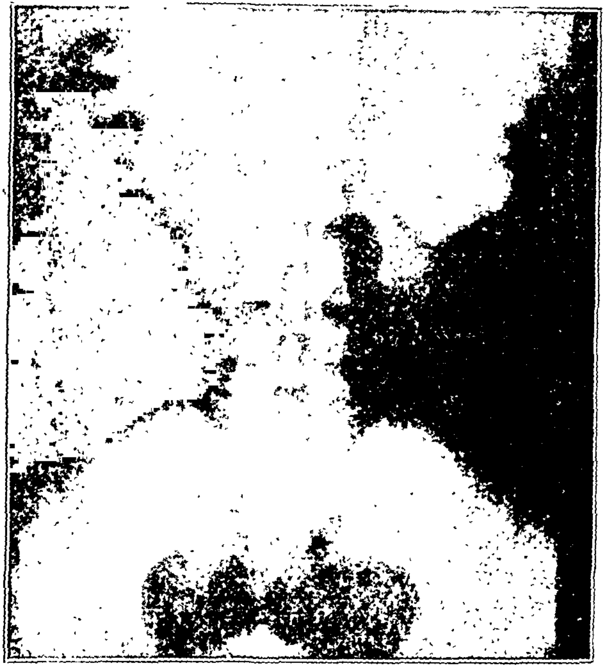

Fig. 1.—Typical ureteropelvic obstruction. Note empty ureter and retained contrast medium in renal pelvis.

In the aforementioned preliminary report the early results of 11 Foley Y plastic[2] operations, following the foregoing principles, were reported. The present report includes these cases and summarizes the findings of 70 ureteropelvic obstructions in 52 patients treated between 1942 and 1946 inclusive. Sixty-two were operated on. Four required nephrectomy. A Foley Y plasty was performed on 45 and the remaining 13 had various other types of operations.

AGE

The ages of these 52 patients ranged from 4 to 63 years. The largest percentage were between 20 and 40 years (61.6 per cent). Although many of these obstructions are congenital, they often go unrecognized for many years. Supervening infection may first attract one's attention to the urinary tract.

[2] Foley, F. E. B.: A new Plastic Operation for Stricture at the Ureteropelvic Junction: Report of Twenty-One Cases, J. Urol. 38: 643-672, 1937.

SYMPTOMS

The frequency of gastrointestinal symptoms in renal disease is attested by the fact that 20 of 52 patients complained primarily of indigestion, flatulence or nausea. In 19 patients, voided urine was normal. This serves to call attention to the fact that one must not eliminate renal disease in the presence of normal voided urine. Urinary symptoms were present in 22, and some renal pain, varying from backache to renal colic, in 46 (table 1).

TABLE 1.—*Symptoms, 52 Patients*

Gastrointestinal (indigestion, flatulence, nausea, etc.)	20
Urinary Symptoms (hematuria, frequency, nocturia, dysuria, etc.)	22
Backache to renal colic (2 days to 14 years)	46
Voided urine normal (remainder, some RBC and WBC)	19
Voided urine after operation normal	25

After operation, the voided urine was normal in 25 patients.

DILATATION OF RENAL PELVIS

The size of the hydronephrosis (grading from 1 to 4) showed that none of the 70 pelves was normal; the larger number (33) were grade 2 before operation. After operation, 11 were shown to be normal and 27 had grade 1 dilatation. Some improvement was noted in practically all cases. There were 18 patients with bilateral ureteropelvic obstruction, but only 9 were subjected to bilateral plastic operations. Renal calculi were present in 12 kidneys.

RENAL FUNCTION

Preoperatively, 13 of 25 patients with ureteropelvic obstructions had diminished function on the affected side, while 12 of 25 had equal function of both kidneys. After operation, 10 of the 13 patients with diminished function were improved according to our functional tests. All patients were subjected to retrograde pyelography and a ten minute delayed roentgenogram taken after the pyelogram. All except 4 showed evidence of delay in eliminating the contrast medium from the renal pelvis.

CAUSES OF URETEROPELVIC OBSTRUCTION

In 44 (71 per cent) of 62 kidneys operated on, the cause of the ureteropelvic obstruction was found to be within the ureter (table 2).

The causative factors included stricture and hypertrophy of the ring (circular) muscle and valves which cause the lumen of the ureter to be diminished in size. In 2 (3.2 per cent), aberrant vessels, bands or adhesions were found to be the sole cause of obstruction. In the remaining 16 (25.8 per cent), both extrinsic causes (aberrant vessels, bands, etc.) and intrinsic causes (stricture, hypertrophy of the muscle or fibrous tissue) were present. It is this last group, in which a combination of factors produced the obstruction, that requires particular diligence in order to make certain that all the obstructive factors are corrected. One must not be misled by the finding of an aberrant vessel or band and fail to search for still another obstructive element within the ureter. To overlook an intrinsic obstruction may lead to progressive damage of the kidney until it is destroyed beyond repair. In our cases, the infrequent finding of aberrant vessels (3.2 per cent) as the only cause of ureteropelvic obstruction suggests the necessity of carefully searching for other causes. Unfortunately, the literature is filled with evidence that aberrant vessels and bands are the most common cause of these obstructions. Our findings coincide with those of Geraghty and Frontz,[3] who, in 1918, found inflammatory contracture and strictures as the almost universal cause of ureteropelvic obstructions. Although Eisendrath and Strauss,[4] in 1921, found accessory vessels in 21 per cent of kidneys at autopsy, their role in producing ureteropelvic obstruction in most cases is questionable.

TABLE 2.—*Causes of Ureteropelvic Obstruction, 62 Cases*

	Number	Percentage
Extrinsic alone (aberrant vessels, bands or adhesions)	2	3.2
Intrinsic alone (stricture, hyperplasia of circular muscle, etc.)	44	71.0
Both extrinsic and intrinsic	16	25.8

OPERATIONS

There were 62 operations performed on 52 patients, 10 having both kidneys operated on. Of these, 39 had 45 Foley Y plastic operations, and of these 9 had resection of the redundant pelvis. The remainder had various types of procedures, as shown in table 3.

In all of the Foley Y plastic operations a nephrostomy tube (Malecot catheter) was used for drainage and a soft rubber splinting catheter was inserted with the nephrostomy tube and passed at least halfway down the ureter. In 29 of these, both tubes were left in place for six weeks or more. Pyelograms at varying intervals, with the contrast medium injected through the nephrostomy tube, gave information about the healing at the ureteropelvic junction. The final results in these 29 cases were: good, 20; fair, 4; and poor, 3. There was no follow-up in 2. When the nephrostomy tube and splinting catheter were removed earlier (or pulled out), the results were somewhat less satisfactory. This indicates that prolonged drainage and splinting are likely to give better results in these plastic procedures.

[4] Eisendrath, D. N.: Hydronephrosis Due to Obstruction of the Renal Pelvis by One or Two Main Renal Arteries, 24: 173-185, 1930.

The larger group of patients (27 out of 45) drained no urine from the nephrostomy wound after forty-eight hours, indicating that adequate drainage down the ureter to the bladder had been reestablished. One urinary fistula developed, in the case in which both the nephrostomy tube and the splinting catheter were inadvertently pulled out on the nineteenth postoperative day. Subsequently nephrectomy was required.

INFECTION

In the group of 45 Foley Y plastic operations, 39 renal cultures were taken, 23 of which were sterile before operation. After operation, 38 renal cultures were taken, 25 of which were sterile. Hinman[5] stated that plastic operations should not be undertaken in infected kidneys. While attempts should be made to eliminate infection when present, our experience suggests that plastic operations can be successfully performed in the presence of renal infection. In some instances it is impossible to eliminate infection in the presence of ureteropelvic obstruction. Furthermore, the newer antiseptics and antibiotics have undoubtedly made these operations safer even in the presence of infection.

POSTOPERATIVE RESULTS

The evaluation of postoperative results is difficult. One is not justified in stating that relief of pain constitutes a successful operation. While relief of pain may be satisfactory to the patient, the surgeon should convince himself that he has improved the drainage from the kidney and has adequately removed the obstruction which was causing gradual damage to the kidney. Relief of pain may occur following complete denervation of the kidney, especially around the ureteropelvic junction. The removal of these nerves may relieve the renal pain, at least temporarily, and satisfy both the patient and the surgeon that no further damage is occurring to that kidney. Other evidence regarding the results should be sought.

Of 39 patients with 45 Foley Y plastic operations, recently questioned, 34 (87.2 per cent) were completely free of symptoms (table 4). Three (7.7 per cent) were not relieved, and 2 (5.1 per cent) were doubtful. Of the patients who had other operative procedures, about half were symptom free and half were unimproved.

TABLE 4.—*Relief of Symptoms After Operation*

	Foley Y Plastic		Others	
	No.	%	No.	%
Yes	34	87.2	6	46.2
No	3	7.7	6	46.2
Doubtful	2	5.1	1	7.6

The postoperative pyelogram was considered by us to be satisfactory in 26 cases (65 per cent) and fair in 10 others (25 per cent), while 4 (10 per cent) showed poor results. In 5 no follow-up was possible.

Thirty-four of these 39 patients were subjected to retrograde pyelograms and a ten minute delayed roentgenogram. In 20 the contrast medium was completely expelled from the renal pelvis, all of whom had shown retention before operation. The remainder still showed some delay in expelling the contrast medium from the pelvis to the bladder.

To evaluate the results properly, one should not be misled by the relief of symptoms alone. Evidence of improved function (11 of 13 cases), and delayed retrograde pyelograms which show improved drainage from the renal pelvis give weight to the success of the operative procedure. Numerous patients have come under our observation after temporary relief of symptoms following severing of aberrant vessels or removal of fibrous bands. A thorough study of many of them revealed that the real obstruction at the ureteropelvic junction had not been relieved and renal damage had continued to progress. In many, the symptoms were temporarily relieved and both the surgeon and the patient considered the result to be satisfactory. In these cases, particularly, subsequent examinations should be continued for prolonged periods to evaluate the results.

One of our early patients had been subjected to surgical procedures on both kidneys three years before he came under our observation. Aberrant vessels had been severed at both ureteropelvic junctions together with the freeing of bands in this area. He was practically free from symptoms for almost three years, when he suddenly experienced left renal colic and anuria. Catheters would pass to neither kidney and an emergency left nephrostomy was performed. Subsequent investigation revealed grade 4 hydronephrosis in each kidney with bilateral intrinsic ureteropelvic obstruction (fig. 2). Plastic repair of both kidneys reestablished drainage, and he has remained well until the present (five and one-half years) (fig. 3).

---

[5] Hinman, F.: Treatment of Hydronephrosis, Southwestern Med. 26: 357-368, 1942.

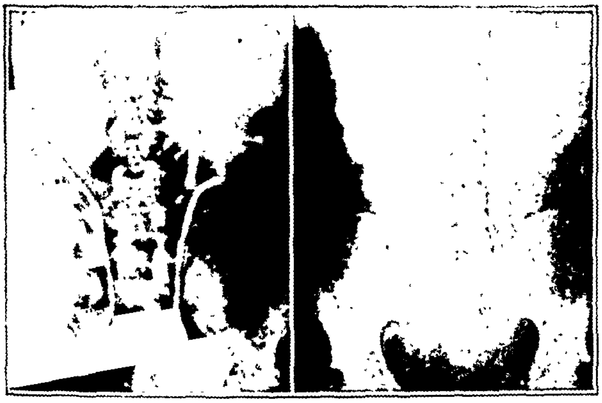

Fig. 2.—Bilateral ureteropelvic obstructions with huge hydronephrosis and complete anuria. Ureter on left was reimplanted in pelvis and Foley Y plastic operation was done on right.

MORTALITY

There were no operative deaths in this series. Two patients have subsequently died, 1 of uremia four years after operation and 1 of cardiac disease and uremia two and one half years after operation. Both of these patients had seriously damaged kidneys before operation and, although the operation may not have prolonged their lives, it is doubtful that it shortened the life of either one.

RENAL CALCULI

Stones were present in 12 of these kidneys before operation. Only 2 of the patients have reformed stones (table 5).

TABLE 5.—*Renal Calculi*

Before Operation	
Present in	12
Absent in	58
After Operation	
Reformed calculi	2
Stones developed after Foley Y plasty	5 11.1% of 45 cases

However, 5 (11.1 per cent) of the 45 who had Foley Y plastic operation later had renal calculi. These may have formed from the prolonged nephrostomy drainage. This hazard should not be overlooked when prolonged drainage becomes necessary. A roentgenogram taken before the nephrostomy tube is removed may reveal the calculus, which sometimes may be dissolved by irrigation and this complication thereby prevented.

OTHER PLASTIC OPERATIONS

Other plastic operative procedures have not been very successful in our hands. Of 13 cases, the results were satisfactory in only 2. Prolonged drainage and ureteral splinting were not carried out in these cases.

NEPHRECTOMY AFTER PLASTIC OPERATION

In this series of cases, only 2 patients have thus far required subsequent nephrectomy. One patient required nephrectomy four months after an unsuccessful Rammstedt plastic operation. Failure in this case may be attributed partly to the fact that the nephrostomy tube and the splinting catheter were removed in twenty-one days. In the other case, nephrectomy was performed six months after a Foley Y plasty. The splinting catheter and nephrostomy tube were inadvertently pulled out on the nineteenth postoperative day and the repair was unsuccessful. A urinary fistula developed and nephrectomy was necessary.

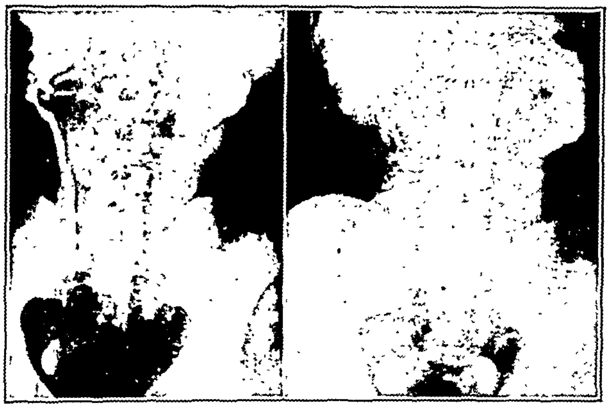

Fig. 3.—Same patient as in figure 2, showing postoperative result.

SUBSEQUENT FINDINGS IN TEN PATIENTS OPERATED ON IN 1942

Of the 7 patients subjected to 11 Foley Y plastic operations (4 bilateral), reported by Henline and Menning in 1942, 7 kidneys remain entirely satisfactory, 2 are considered fair, and 2 poor. These results compare favorably with reports by Moore[6] and Walters, Cabot and Priestly,[7] who reported about 20 per cent failure. Our 2 failures were in 1 patient who had previously had a Rammstedt repair on his right kidney with drainage for only fifteen days. Subsequently Foley Y plastic repair on both organs failed to save his severely damaged kidneys, and he died four years later.

COMMENT

Although each case of ureteropelvic obstruction must be considered individually, experience suggests that the greatest number of cases result from actual narrowing within the ureter as it leaves the renal pelvis. This stenosis may be difficult to visualize even after the renal pelvis and ureter are exposed at operation because it is the caliber of the lumen of the ureter which must be determined. The ureter may be normal in appearance from the outside but constricted within. One should not be content to sever aberrant vessels or adhesions or bands, but should also determine the caliber of the ureter. Unless this is faithfully done in each case, the results will be disappointing in many instances.

---

[7] Walters, W.; Cabot, H., and Priestley, J.: Operative Results in Non-Calculous Hydronephrosis: Results in Seventy-One Plastic Operations, J. Urol. 38: 688-693, 1937.

Not all patients with hydronephrosis have ureteropelvic obstructions. A stenosis in the midureter or at the ureterovesical junction will produce hydronephrosis. It is even more common to find a dilated renal pelvis resulting from a small stone lodged along the ureter. Therefore, accurate localization of the obstruction at the ureteropelvic junction is essential before treatment be undertaken.

An excretory urogram may indicate obstruction at the ureteropelvic junction. However, it is our practice to rely only on retrograde pyelograms for the diagnosis of these obstructions. Cystoscopy permits an evaluation of divided renal function and, at the same time, the taking of bilateral pyelograms. The size of the hydronephrosis and the area of obstruction are more clearly outlined. A ten minute delayed roentgenogram after pyelography will reveal retained contrast medium in the renal pelvis. It is typical for the renal pelvis to be well outlined in this roentgenogram, but the ureter is usually empty of contrast medium. One may, therefore, rely on the obstruction's being present at the junction of the ureter with the pelvis.

The operative procedure should adequately correct the deformity. In some instances, various other operations are necessary to attain this result, but in our experience the majority of cases lend themselves to the Foley Y plastic repair. The exact type of repair is probably less important than the longitudinal incision of the stenosed area, with prolonged nephrostomy drainage and use of the splinting catheter. Davis[8] has advocated only the incision of the stenosed area, but has insisted on splinting the ureter for sufficient time to permit it to proliferate and grow around the splinting catheter. He called this procedure "intubation" and reported good results in his cases. Cabot,[9] Ormond[10] and Foulds, among others, advised prolonged drainage and ureteral splinting, with which Davis and we agree. The ureteral catheter acts as a scaffold around which the ureter may re-form and Gibson[11] compared its use to the use of a splint in a fractured bone by the orthopedic surgeon.

Unless necessity demands, we prefer not to sever the ureter completely from the pelvis and reimplant it in a dependent portion of the pelvis. In a few cases this has been necessary, but our results indicate that, at least for some months, the renal pelvis will not drain as well as in those cases in which the ureter has only been incised longitudinally. It is our impression that, at least temporarily, the severed nerves prevent normal peristalsis.

Although our results in this series of cases are not all that one would desire, they are far superior to those achieved in cases in which these principles were not followed. Our attempt should be to reestablish renal drainage, thus preventing continued renal damage and conserving the remaining functioning renal tissue.

SUMMARY AND CONCLUSIONS

Gastrointestinal symptoms, even in the presence of normal urine, may indicate an obstructive renal syndrome. The diagnosis of obstruction at the ureteropelvic junction is made by retrograde pyelography with, in addition, a ten minute delayed roentgenogram. Most ureteropelvic obstructions are due to narrowing of the lumen of the ureter even though aberrant vessels, bands and adhesions may also be present.

Plastic operations should only be performed when sufficient renal tissue remains to sustain life. The Foley Y plastic operation has been more successful in our hands than other procedures, but only when combined with nephrostomy drainage and the use of a splinting ureteral catheter for six weeks.

Results should be evaluated, not by relief of symptoms alone, but by improved renal function and evidence of improved drainage of the renal pelvis by retrograde pyelogram and a delayed roentgenogram. These patients should be followed for several years before final results are tabulated.

The operative mortality should compare favorably to that in other renal surgery.

Renal calculi may form during prolonged nephrostomy drainage and, if discovered before the tube is removed, may occasionally be dissolved by irrigation. Subsequent nephrectomy became necessary in 2 cases. Poor results were obtained in 10 per cent of the cases followed. Satisfactory results, or improvement, were obtained in the remaining 90 per cent of cases.

ABSTRACT OF DISCUSSION

DR. JOHN M. PACE, Dallas, Texas: Dr. Herbst has brought to us an instructive paper on a most unusual and rarely recognized anomaly. That the incidence of the posterior renal pelvis is low is brought out by his study of postmortem material which failed to demonstrate the anomaly in one hundred anatomic examinations. The urographic description of the gun barrel pelvis with the ureter lateral to the medial border of the kidney is important; however, this roentgenographic picture was not constant. Should one suspect a posterior pelvis in a kidney which meets the usually accepted criteria for nephropexy, I feel that the patient should be advised that a nephrectomy may be deemed advisable for the reasons so admirably given by Dr. Herbst. Dr. Herbst is to be congratulated for bringing to our attention a renal anomaly which has not been previously recognized as a hazard in nephropexy.

DR. CLARK M. JOHNSON, San Francisco: In unilateral ureteropelvic obstruction, any type of repair is doomed to failure in the presence of complete compensatory hypertrophy of a normal mate. This is determined by roentgen evidence and accurate estimation of the relative function. Dr. Henline's observation that any kidney which shows evidence of being able to sustain life in the absence of its mate is merely another way of stating the same thing. At the original examination one may find the function greatly reduced on the affected side. By leaving a ureteral catheter in place for twenty-four to forty-eight hours and rechecking the function of the separate kidneys, one may find even in this short length of time considerable improvement in the function of the affected kidney. This is good evidence that the mate is not completely hypertrophied and that the affected kidney may be saved. I wish to stress that there is no one method of relieving all types of ureteropelvic obstructions. I do not concur with those who use small splints but prefer the largest splint that the ureter below the obstruction will admit. I do not believe that it makes any difference what type of repair is used, as long as the obstructing area is incised longitudinally and the redundant pelvis resected, giving a good funnel-shaped outlet. I prefer to use few or no sutures, and in most instances leave the incised ureter wide open over the splint. It is true that simple division of aberrant vessels or bands will not relieve most obstructions because there is usually an intrinsic narrowing of the ureter due to muscular hypertrophy which is not obvious from the surface. This may be congenital and the sole cause of the hydronephrosis, or secondary to the external pressure and the increased muscular effort required in peristalsis. The presence of infection does not mean that the obstruction cannot be relieved and function restored. This is particularly true when the obstruction is bilateral. The principles of repair as set forth by Dr. Henline, using nephrostomy and ureteral splinting, will be successful in most cases, provided that proper cases are selected. As yet one cannot be certain from the tests at hand which cases are amenable to repair. This must often be left to the surgeon's judgment at the time of operation, and even then one may be wrong.

DR. JAMES SARGENT, Milwaukee: Roy Henline was one of the pioneers in plastic surgery in hydronephrosis. He has made one particularly important point, and that is that aberrant blood vessels and bands of adhesions play a relatively unimportant role in hydronephrosis. The disease is caused primarily by an anatomic atresia at the ureteropelvic junction. Proper correction depends on reopening of the lumen of the canal whether or not an aberrant vessel is present. He has made another point that is extremely important. That is the fact that gastric symptoms often are important and sometimes are the only symptoms indicative of hydronephrosis. I recall an officer in the Navy who had hidden his history of nine years of dyspepsia in order to get into the service. Under heavy duty, he broke down and was more or less constantly on the sick list. He had repeatedly negative gastrointestinal and gallbladder studies, and finally came up for medical discharge. Excretory urograms were run and a fairly sizable hydronephrosis found. Its correction relieved his dyspepsia for the first time in ten years. There was nothing in that man's clinical history that would have led any one to suspect that he had had hydronephrosis - except dyspepsia. Both Dr. Henline and Dr. Johnson have stressed the value of plastic surgery in hydronephrosis. Any kidney that has any life in it at all, provided it does not have a prohibitive pathologic condition, should undergo a surgical corrective procedure. I am sure that I want to go along with the two preceding speakers on the size of ureteral catheter splints and the length of time that they are left in. The service of the catheter splint is one of alinement during the time that postoperative fixation of tissue occurs, and unless there is extravasation at the site of the plastic operation, the tissues are fairly well set within a matter of days. In my experience splinting for eight or ten days has proved adequate, and the smaller the inlying splint, the better.

DR. DAVID M. DAVIS, Philadelphia: As I look back to what ureteropelvic surgery amounted to twenty-five years ago, I am amazed at the progress that has taken place. It has taken place gradually, so that one does not notice it from year to year but it is a fact that twenty-five years ago ureteropelvic surgery was entirely the property of a few daring souls. Too often when one kidney was affected nephrectomy had to be performed. When both kidneys were involved, one had to be content with palliation, which did not do much to prolong the patient's life. Now, everything is changed. Dr. Henline and his associate produce a series of cases in which they obtained successful results in 65 per cent by any criterion and in 90 per cent so far as obtaining relief of symptoms is concerned. That changes the entire status of things. We are no longer privileged to wait and watch in cases of hydronephrosis, even though the hydronephrosis be slight, even though the symptoms be slight, even when there is no infection. Many times it is the onset of infection which causes symptoms to arise. Now, we are faced with an entirely different problem, and a much more congenial one, I am sure, to every surgeon; that is to find out the best way to operate on these patients and get the largest percentage of success. I am confident that in another twenty-five years the percentage of success will rise even higher than it is now. I am one of the most enthusiastic devotees of using splints, and at the meeting of the American Urological Association we hope to present a "roundup" of all of of our results in human patients as well as in experimentation on animals. These experiments will be interesting to everybody, whether believers in sutures or not, because they will show some data on exactly how the ureter heals in the presence of a splint, and with or without the removal of a good deal of tissue from the ureteral wall; what happens when the splint is left exposed to the periureteral tissues and how the ureter reconstructs itself and how long it takes. These data may help us to solve the question which Dr. Sargent has mentioned, what is the best length of time to leave the splint in place and what is the best size of splint to use.

DR. THOMAS D. MOORE, Memphis, Tenn.: Dr. Henline has presented an excellent review of his extensive experience in the conservative treatment of hydronephrosis. In the differential diagnosis of hydronephrosis not only is normal urine common, as mentioned by Doctor Henline, but also a preliminary roentgenogram frequently reveals nothing abnormal. The combination of these two negative findings thus may become misleading and guide one away from consideration of the urologic problem. Several years ago I was invited to contribute to a symposium on hydronephrosis by discussing the late results of conservative surgery. A review of the literature at that time revealed approximately 20 per cent failures. Therefore, when confronted with the problem of conserving the hydronephrotic kidney there was 1 chance in 5 that a conservative plastic procedure would not be successful. The figures presented by Dr. Henline indicate a definite change for the better, due perhaps not only to improved technic but to a wiser selection of cases and to a better means of controlling infection by the judicious use of chemotherapy and antibiotics. The prospects for a good result from conservative surgical treatment are not nearly so good when dealing with hydronephrosis of the intrarenal type, in which the dilation is confined chiefly to the calices. This type of hydronephrosis is accompanied by more parenchymal damage and thus a greater degree of impairment of renal function. The extrarenal type of the disease is more amenable to conservative efforts. It is always interesting to hear the report of successful cases; the failures should be equally or more interesting. In the discussion of causes of failures much can be learned. I recall a case in which the immediate result seemed promising but unfortunately I underestimated the importance of an adynamic ureter. The hydronephrosis was of a large extrarenal type in which the ureter appeared decidedly stenosed at the ureteropelvic juncture, below which it followed a tortuous course, accompanied by moderate ureterectasis. At operation the stenosed segment was resected and the ureter reimplanted in the pelvis. In spite of this the hydronephrosis was progressive and after a year nephrectomy was necessary. A year later a retrograde ureterogram revealed persistence of the pronounced degree of diffuse ureteral dilatation It was evident that the adynamic ureter was the probable cause of failure in this case.

DR. A. HYMAN, New York: It seems to me that the pediatricians are still remiss in recognizing these conditions. Despite all the articles and books that have been published on pediatric urology, the pediatricians often fail to make the diagnosis of congenital hydronephrosis. When they have a child with normal urine, they seem to forget that such a condition can exist. In a number of cases in children that we have had, the only symptoms have been abdominal cramps. A few of these children have been operated on for appendicitis. So I think this point should be brought home to the pediatricians. Some men believe in splinting for six to eight weeks, and longer. Others splint for eight to ten days. In a few articles, there is no mention of splinting at all. I was interested to hear Dr. Davis say that they are doing experimental work along these lines, because there has been little experimental work to tell us just what the changes are in the ureter and the process of healing and how long these ureters should be splinted. I am getting away from the long splinting and feel that two weeks at the most is sufficient. As to the second question, is it necessary to resect a redundant pelvis? In going over the literature, a number of men think it is necessary to do so and others do not. I feel that a large redundant pelvis should be resected. We should be more and more conservative in the surgery of hydronephrosis, especially now that we have antibiotics and sulfonamide drugs. Where previously nothing much could be done to combat infection, with these methods at our disposal the results of plastic procedures should be better and better as the years go by.

DR. WILLIAM P. HERBST, Washington, D. C.: I want to thank Dr. Pace for his discussion and to describe one aspect of the mobilization of these kidneys. As one mobilizes a kidney, the thumb falls into a depression in the posterior wall. This makes the diagnosis.

DR. ROY. B. HENLINE, New York: I am extremely pleased that this paper brought forth so many comments, regardless of whether they agreed or not. I am also pleased that some of them did agree to a great extent That was the primary purpose of this presentation. Dr. Johnson made two or three interesting points which I thoroughly agree with but which were perhaps expressed in just a little different way. I agree that the larger splinting is preferable. I have never seen any untoward effects from use of as large a splinting catheter as would fit down the ureter. In other words, I have never seen any evidence of necrosis or damage to the ureter following this procedure. I believe Dr. David Davis' experimental work will help solve the problem as to how long the splinting catheter should be left in place. I am convinced that in none of these cases can the sutures be watertight and that there is always some leakage at the suture line which is minimized by the nephrostomy drainage. On the other hand, as these sutures are absorbed the approximated edges should heal sufficiently to prevent further urinary extravasation. This is benefited by nephrostomy drainage which promptly drains the secreted urine and prevents any pressure within the renal pelvis. If the approximated edges are sufficiently healed before the nephrostomy tube is removed, there will be no urinary leakage to produce scar tissue around the repaired area. However, this problem will probably be solved by experimental work, some of which Dr. Davis has done I want to thank you all for the excellent discussions that this has provoked, and, if nothing else has been left in your mind from this presentation, I hope that we may no longer hear from the urologist particularly, and also from the roentgenologist, that there is a ureteropelvic obstruction caused by an aberrant vessel. I think that should be deleted to a great extent from the literature

---

Queen Victoria and Lord Lister.—On one occasion Lord Lister told me that Queen Victoria had written to him and asked him, as president of the Royal Society, to do all in his power, by speaking and writing, to stop vivisection. He knew that his reply would be very disappointing to the Queen. He sent a very carefully worded reply, saying that it was a vital necessity for the good of Her Majesty's subjects that vivisection should be allowed to continue He further respectfully assured the Queen that vivisection in this country was under the careful supervision and control of Her Majesty's Government. After receiving this letter the Queen took no further notice of him —Cheatle, Sir Lenthal, Annals of the Royal College of Surgeons of England, January 1948.

Clinical Notes, Suggestions and New Instruments

HYPERKERATOSIS AND ONYCHOLYSIS AFTER USE OF NEW NAIL COSMETIC

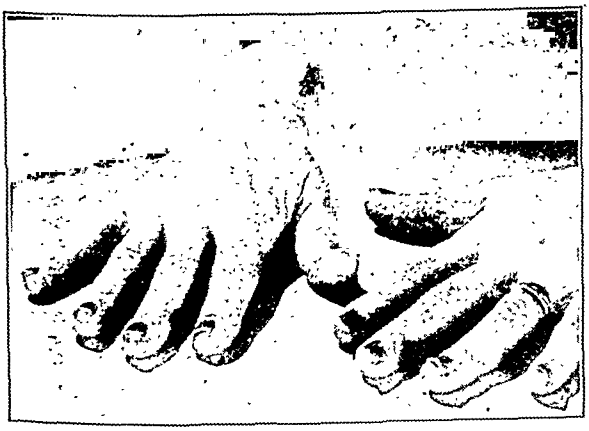
S. J. FAHBERG, M. D.
Newark, N. J.
and
HERMAN SHARLIT, M. D.
New York

A new product "everon" has recently been introduced for use in lacquering nails. Apparently it is applied to the nail before the enamel for the purpose of producing a better adhesion of the enamel to the nail substance. The chemical nature of this product is not known to us beyond the fact that it contains some synthetic resins.

Two patients are the basis for this report; their clinical condition and history are virtually identical:

Within three days of the use of "everon" (in one after a first application and the other after a fourth application) the tips of all fingers became tender and slightly swollen; then followed changes in all fingers leading to subungual hyperkeratosis and the beginning in some nails of onycholysis. Attempted removal of the enamel even within a week of its application disclosed a permanent staining of the nail.[1]

Patch tests with "Everon" on both these patients elicited positive reactions.



Showing discoloration of nails in case 1.

A photograph of the nails in 1 case is supplied. Note the discoloration which remains after the enamel has been removed with the usual solvents.

Opportunity has not as yet been afforded to study or analyze the mechanism of the production of the damage. The severity of the damage and the length of time required for recovery—if complete and permanent recovery does ensue—demand quick publicity of these facts to bring a halt to continuing exposures.

---

[1] The discoloration was revealed to be blood pigment on undersurface of nail.

SUBACUTE BACTERIAL ENDOCARDITIS

Report of Two Cases

JAMES R. REULING, M.D.
Bayside, N. Y.
and
CHARLES CRAMER, M.D.
Jackson Heights, N. Y.

One of the remarkable discoveries of medical science has been penicillin, and probably the best example of its value is in the treatment of subacute bacterial endocarditis. Any doubt that there was reason to dread the disease will be quickly dispelled if one reads the report of the cases from Peter Bent Brigham Hospital.[1] From 1913 to 1937 there were 237 cases with no recovery. Almost universally the experience with subacute bacterial endocarditis has been the same, although Libman and Friedberg[2] reported 4 per cent spontaneous cures.

Up to four years ago subacute bacterial endocarditis was considered an incurable disease; the percentage of cures has been changed, and at present over 90 per cent of patients with the disease recover when sufficient penicillin is used. When one meditates on the fact that the early reports stated that penicillin was ineffectual in the treatment of subacute bacterial endocarditis, the importance of carefully recorded laboratory and clinical data becomes obvious.

REPORT OF CASES

CASE 1.—T. W., a 36 year old Negro, was first admitted to Flushing Hospital on March 24, 1944. One week before admission he was awakened during the night with sudden substernal pain. For seven hours the pain was severe, radiating to the right side of the neck; after this the pain gradually lessened. The patient stated that he had had fever, but did not know how high his temperature had been. The past history was significant in that he had had rheumatic fever at the age of 14 years and suffered recurrent pains in the joints for the subsequent three years. Three weeks prior to admission he had "rheumatic pains" in both knees, lasting two weeks.

Examination revealed a well developed muscular man who was in no acute distress. The temperature was 100.2 F. (rectal). No petechiae, Osler nodes or Janeway spots were noted. Examination by percussion revealed the heart to be enlarged on the left side (later confirmed by roentgenogram). The rhythm was regular and the rate 88 beats per minute. A loud harsh systolic murmur was heard over the mitral area transmitted laterally and posteriorly. No diastolic murmur could be detected. The lungs were clear. Liver and spleen were not palpable. No enlargement of the joints was noted, but the knees were tender on motion.

On admission the white cell count was 14,050, with 82 per cent polymorphonuclear leukocytes. The hemoglobin content was 76 per cent (12.9 Gm.). The urine was normal, and the Kahn reaction was negative. The temperature ranged between 100 and 102.6 F. On the fourth hospital day treatment with sodium salicylate in full doses was started, but no drop in temperature or subjective improvement resulted. On April 3, blood culture revealed Streptococcus viridans, 400 bacteria per cubic centimeter.

Since the supply of penicillin was limited and preliminary reports on the treatment of subacute bacterial endocarditis with penicillin were unfavorable, the drug could not be obtained. It was, therefore, decided that sulfadiazine be given while attempts were made to obtain penicillin from the National Research Council. On April 5, the thirteenth hospital day, sulfadiazine therapy was started. The initial dose was 4 Gm., followed by 2 Gm. every four hours for four doses and 1 Gm. every four hours thereafter. The drug was given for sixteen days, and satisfactory levels of sulfadiazine in the blood, ranging from 10.5 to 21.3 mg. per hundred cubic centimeters, were obtained. After forty-eight hours of treatment with sulfadiazine, the temperature dropped to normal and remained so. In spite of the fact that the temperature remained normal for two weeks, two repeated blood cultures revealed S. viridans. Treatment with sulfadiazine was discontinued at this time, and during the following eight days the temperature began to rise slowly. Also during this eight day period, six more blood cultures were reported positive for S. viridans.

---

[1] Favour, C. B.; Janeway, C. A.; Gibson, J. G., and Levine, S. A.: New England J. Med. 234: 71-77, 1946.

[2] Libman, E., and Friedberg, C. K.: Subacute Bacterial Endocarditis, edited by H. A. Christian, New York, Oxford University Press, 1941.

Penicillin therapy was started on the thirty-seventh hospital day, nine days after the termination of treatment with sulfadiazine; 200,000 units were given daily for thirteen days, for a total of 2,600,000 units. Within twenty-four hours after treatment with penicillin was started, the temperature dropped to normal again and continued normal for the remainder of his hospital stay. During this thirty-three day period, eighteen additional blood cultures were obtained and all were reported negative.

Following discharge the patient attended the cardiac clinic and remained asymptomatic. On June 27, approximately seven weeks after termination of penicillin therapy, the blood culture again revealed S. viridans.

Because of the difficulty in obtaining penicillin, the patient was sent to the Queens General Hospital, where another course of penicillin was administered. This consisted of 2,500,000 units given in a daily divided dose of 200,000 units, which was almost identical with the previous course, and again the blood cultures became negative. The patient was followed up in the Flushing Hospital Cardiac Clinic after his discharge from Queens General Hospital.

Blood cultures on September 19 and October 3 were positive for S. viridans. The patient was hospitalized in Flushing Hospital, where the third and last course of penicillin was given. The supply of penicillin had been increased considerably, and although the same daily amount, 200,000 units (16,000 units every two hours), was given, treatment was continued for a longer period of time, namely, for thirty-nine days. During this time a total of 7,800,000 units were given. The blood cultures became sterile immediately after treatment was resumed and have remained sterile during the past three years (to date of writing).

Case 2.—W. G., a 53 year old white man, three weeks before admission experienced severe sinusitis accompanied with considerable drainage, fever and pains in the lower part of the back and in the legs. When the fever continued he was hospitalized by his physician. One blood culture was reputedly negative. Penicillin was given, the dosage being 50,000 units every three hours for two days, followed by 30,000 units every three hours for five days. After two days of penicillin therapy the temperature returned to normal, and the patient was discharged four days after the seven day course of treatment with penicillin. Two days after his discharge the fever returned, and he was seen by one of us (C. C.) and admitted to Flushing Hospital on Nov. 25, 1946.

Examination revealed a well developed man with warm skin and in no acute distress. The temperature was 102 8 F. (rectal). No embolic phenomena were discovered. Examination by percussion revealed that the heart was not enlarged; this was confirmed later by a roentgenogram. The rhythm was regular, and the rate was 102 beats per minute. A long rough systolic murmur was heard over the precordium transmitted to the axilla and the neck. The liver and the spleen were not palpable.

On admission the white cell count was 7,050, with 74 per cent polymorphonuclear cells. The urine was normal. Three blood cultures made on the first three hospital days revealed Streptococcus viridans. Sensitivity to penicillin was evidenced with .08 unit per cubic centimeter.

From the day of admission, November 25, to November 29, the daily temperature range was between 99 and 103.4 F. Treatment with penicillin was started on November 29, and within twenty-four hours the temperature dropped to normal. The temperature continued to be normal for the remainder of his hospital stay except for three rises to 101.4, 101 and 102 F. on December 10, 22 and 27, respectively. On several occasions he complained of pains in the tips of his fingers and toes, but other than tenderness to pressure no objective signs were observed. There was no correlation between the three elevations of temperature during treatment and the tenderness of the tips of the fingers and toes.

Penicillin was administered as follows:

Units	Interval (Hr.)	Duration
100,000	3	24 hr.
71,400	3	48 hr.
62,500	3	9 days
41,600	2	28 days
30,000	2	5 days

All penicillin was given intramuscularly. The longest period of treatment was for thirty-seven days, with 500,000 units being given every twenty-four hours. During this period the frequency of injection varied from every three hours for nine days to every two hours for twenty-eight days

COMMENT

The value of in vitro sensitivity tests performed on the isolated organism has been proved. The treatment in the first case presented was carried out while these tests were still in the experimental stage and before their definite value had been demonstrated.

Although the response indicated a sensitive organism, actually the patient conducted a sensitivity test in vivo. The first two courses, when approximately 2,500,000 units of penicillin were given, sterilized the blood stream but not the growth on the cardiac valve The third and last course of penicillin produced a cure, and, although the daily amount was the same, it was given over a much longer period of time than the two previous courses. In this respect observations in this case differ from those usually reported by other authors.[3]

We cannot explain the response of the first patient to penicillin in the prolonged third course, with the same daily dose being used. For best results sufficient daily dosage should be given to raise the level of the drug in the blood to at least five times the sensitivity level of the organism.[1]

There can be little doubt that the first patient is cured. He has been well from a clinical and bacteriologic standpoint for over three years. He has been engaged in a gainful occupation for the past year and a half, working actively in a laundry. He has never had any signs of congestive cardiac failure and is now completely free from symptoms. The question arises as to the length of time which must elapse before a patient can be considered cured. According to Christie[5] relapses usually occur within thirty days after cessation of treatment and are rare after fifty days. Hunter[4b] expressed the belief that if the blood cultures made during the first two weeks after completion of treatment remain sterile one can be reasonably hopeful of cure.

In the first case presented the blood culture again became positive seven weeks after treatment with penicillin was stopped and four weeks after the second course was given.

In the second case, after a brief incomplete course of penicillin was administered at another hospital, the patient responded to a single course with large daily doses. Because of the occasional rise in temperature and pains in the tips of the fingers and toes, treatment was continued for forty-five days. According to Hunter,[4b] who stated preference for large daily amounts for three weeks, some patients continue to have fever, elevated sedimentation rate, leukocytosis and embolic phenomena for several weeks.

It seems reasonable to assume that the second patient also is cured. The last positive blood culture was made Dec. 11, 1946, nine months prior to the date of writing, and the patient has been clinically well since that time.

Penicillin fastness probably does exist, but it has been overemphasized. As more statistics accumulate, one seems justified in stating that the number of instances of resistance to penicillin is small. The first case presented offers a striking example of this fact. Although no increase in daily dosage was used, the organism proved sensitive after the third course of penicillin.

The upper limit of human tolerance to penicillin has not been determined. Hunter[4b] stated that doses as high as 20,000,000 units a day have cured the disease in some patients, when treat-

ment for many months with from 2,000,000 to 10,000,000 units daily has failed. Loewe[6] treated 5 patients with 40,000,000 units per day; 3 of these recovered.

While the penicillin sensitivity test is a relatively simple one and can be performed in all laboratories without difficulty, the same cannot be said of determination of the level of penicillin in the blood. This latter test can be performed when a standard organism is involved. Unless considerable work is being done on this type of disease, it may not be found practical in every hospital to conduct determinations of the levels in the blood. In such circumstances, as in the second case presented, it becomes necessary that arbitrary decisions be made. For sensitivity up to 0.1 unit of penicillin per cubic centimeter a dosage between 500,000 and 1,000,000 units in twenty-four hours usually proves efficacious. According to Dawson and Hunter[5] a daily dose of 300,000 units administered by constant intramuscular drip produced an average serum level of 0.2 unit per cubic centimeter, with a range of values from .025 to 0.8.

HODGKIN'S DISEASE COMPLICATED BY PREGNANCY

JOHN E. SUMMERS, M. D.*
and
WELLS C. REID, M. D.
Goodrich, Mich.

Forty-nine infants borne of mothers with Hodgkin's disease have been reported in the literature.[1] We wish to report a case of a mother with Hodgkin's disease who has borne 2 children, making a total of 51 infants so far reported.

Report of Case

The patient was first seen in the outpatient department of the Goodrich General Hospital on July 3, 1939, at the age of 15 years, with chief complaints of nausea, vomiting and abdominal pain of five days' duration. She had not menstruated. At the age of 11 she had been raped and had contracted gonorrhea which had been successfully treated elsewhere. Findings were negative at this time except for a few red blood cells and white blood cells in the urine.

She was again seen in the outpatient department on Jan. 6, 1940, with similar complaints except that there had been no vomiting and the symptoms had been present only two days. Her temperature was 100 F., pulse rate 100 per minute and respiration rate 25 per minute. There was tenderness over the urinary bladder. Urinalysis showed a few red blood cells and white blood cells. Examination of the blood revealed a leukocyte count of 11,900 with 51 per cent polymorphonuclear cells, 3 per cent stab forms, 33 per cent lymphocytes, 8 per cent monocytes and 5 per cent eosinophils.

Four years later, on March 19, 1944, the patient was seen with the complaint of a growth in the lower part of the left side of her neck. She had first noted this tumor after Christmas in 1943, at which time it was about the size of a hickory nut (1¼ to 2 cm.). At the time of examination the tumor was about 4 cm. in diameter and was freely movable. Her temperature was 99 F., pulse rate 102 per minute; the blood leukocytes were 12,800, the urine was normal and a roentgenogram of the chest and the reaction to a blood Kahn test were negative.

On April 3, 1944, two large left supraclavicular nodes were removed. The pathologist's report on this tissue was: "Lymphoblastoma of the Hodgkin's disease type. Eosinophils were present in unusual numbers. There were numerous Dorothy Reed giant cells and early fibroblastic proliferation." The patient was sent to the University Hospital at Ann Arbor, Mich., for roentgen therapy. At Ann Arbor no other evidence of the disease, except for the left supraclavicular nodes, could be found.

She returned to us on June 2, 1946, for a marriage certificate. On July 16, she was found to be eight months pregnant, and the left supraclavicular nodes were again found to be enlarged. She was advised to return to Ann Arbor for further treatment but did not cooperate well, taking only one of the six proposed roentgen treatments. However the pregnancy progressed normally. The maximum blood pressure reading was 108 systolic and 55 diastolic; the maximum weight, 179 pounds (81.2 Kg.); the urine was normal on all occasions. At 12:45 p.m., on August 23, the patient delivered a normal-appearing, 7 pound (3 175 Gm.) baby girl. The postpartum course was uneventful except for a daily elevation of temperature to 100 F. The mother and baby were discharged from the hospital on September 1.

On December 9, the left supraclavicular nodes were again found to be enlarged. At this time examination of the blood revealed: red blood cells, 4,300,600; hemoglobin, 85 per cent, and white blood cells 11,180, with 41 per cent polymorphonuclear cells, 10 per cent stab forms, 26 per cent lymphocytes, 11 per cent mononuclear cells, 10 per cent eosinophils and 2 per cent basophils. She was advised to return to Ann Arbor for more roentgen therapy.

The patient returned on March 12, 1947, with complaints of bloating of the stomach, nausea and vomiting, difficulty in swallowing and regurgitation of food. She was again pregnant. Her weight was 146 pounds (66.2 Kg.). Fluoroscopic examination of the esophagus, stomach and duodenum during the ingestion of a barium meal on April 4 gave negative results. There were no signs referable to a toxemia of pregnancy.

The second pregnancy was complicated by these gastrointestinal disturbances. At 9:20 p.m., on June 3, the patient delivered a 3 pound, 15¼ ounce (1,800 Gm.) boy. During her hospital stay post partum the mother showed a daily elevation of temperature to, or above, 100 F. The mother left the hospital against advice; the baby was discharged, in good condition, on August 1.

On August 11, the patient returned to us with the complaint of vomiting everything that she attempted to eat. She was 23 years of age and weighed 100 pounds (45.4 Kg.); (her maximum, nonpregnant weight had been 154 pounds [69.9 Kg.]). The patient was returned to Ann Arbor, where she was hospitalized from August 12 to August 24. On a regimen of bed rest, supportive therapy, tincture of belladonna and phenobarbital she improved and gained 12 pounds (5.4 Kg.) weight.

At the present time (March 27, 1948), the patient is still doing her housework and her 2 babies are developing normally.

DISPOSABLE, FINE MESH FILTER FOR BLOOD AND PLASMA

WARREN B COOKSEY, M. D.
and
G. CLARE PUSCHELBERG
Detroit

The earliest investigations into the properties of stored blood for purposes of transfusion clearly revealed the necessity for careful filtration of such material before use. That fibrin particles, clumps of white blood cells or disintegrated platelets, and even small blood clots were to be expected in blood stored over a relatively few hours was quickly apparent.[1] However, a few deaths with multiple pulmonary emboli from this material were reported before the extreme importance of adequate filtration of stored blood and plasma was fully appreciated. A common method of filtration in the early days was that of simply pouring the blood through several layers of ordinary sterile gauze.[2] This method, of course, was clumsy, open to contamination and inadequate in removing small particulate matter. Furthermore, considerable cotton lint was always added to the filtrate. Undoubtedly, many of the so-called pyrogenic reactions to transfusions in the early days of blood storage were due to the numerous small particles which were not removed before injection.

After many materials such as rayon, bolting silk,[1] glass beads,[3] "fiberglas" and various grades of metal cloth[4] were extensively tried, it became apparent that "monel" or stainless steel wire cloth filters of adequate dimensions were, on the whole, most suitable. As a rule, 100 to 200 mesh stainless steel wire cloth, formed into closed cylinders and enclosed in a glass housing, were used. The cost of such stainless steel filters was such that repeated use was, of course, necessary, and hence the problem of efficient cleaning of these filters each time after use became difficult and the procedure somewhat costly. Considered opinion from numerous sources indicated that even after scrubbing with a fine brush these filters had to be soaked several hours in concentrated nitric acid, then rinsed several times in fresh, distilled water before they could be considered at all pyrogen free. Obviously, an inexpensive and disposable blood filter, possessing the necessary qualities of fineness, nontoxicity and ease of adaptibility to the present transfusion equipment, has been greatly needed.

Just before the close of World War II, having tried all the materials mentioned, starting with the earliest days of blood banking, and finding none entirely suitable, we were fortunate in procuring a "bakelite"-impregnated filter paper, prepared by the Fabricon Products, Inc., of Detroit. Though this early material did not prove suitable for blood transfusion purposes, nevertheless, the principle of phenolic resin impregnated materials for filtering seemed so clearly applicable to blood filter construction that a search for a more suitable base was begun at once. With salvaged red blood cells from the wartime Red Cross blood donor service, dozens of fabrics were tested. It was finally apparent that cotton cloth constructed with threads of sufficiently small dimension and uniformity, and of a mesh of 90 to 100 squares per inch, when impregnated with heat-hardening "bakelite" resin, was ideal for filtering human blood. Because of the characteristic of polymerizing under heat to a fixed contour, it was possible to pleat such filters, thus more than doubling the filtering surface of a given cylinder and also providing a more efficient filtering contour. All lint contained in the cotton fabric was completely bound by the resin and, indeed, provided an additional barrier to even the smallest particle of fibrin or clot.

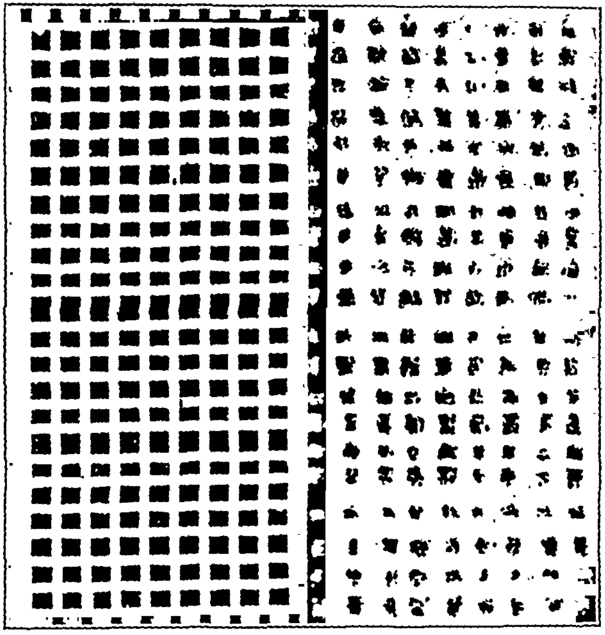

Fig. 1.--Left, standard 100 mesh stainless steel wire cloth. Right, "bakelite"-impregnated cloth used in disposable filter.

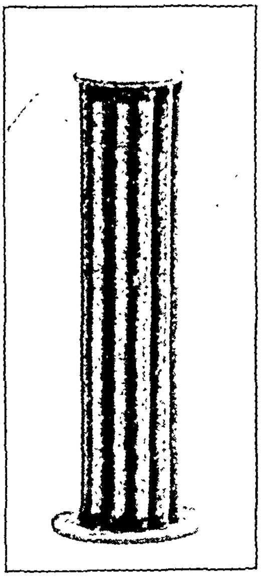

Fig. 2.--Finished "bakelite"-impregnated filter.

While phenolic resins have had numerous applications in medicine and have proved their relative

insolubility in injectible or body fluids and have shown no toxicity by any ordinary contacts with human tissue, nevertheless, before these filters were actually used for transfusions, careful animal testing was carried out by intravenous injection into rabbits of dextrose and sodium chloride solutions in which one of the standard filters had been autoclaved and allowed to stand for twenty-four hours before injection. Several times filters were placed in 1 liter flasks of 5 per cent dextrose and sodium chloride solution, then autoclaved, after which the dextrose and sodium chloride solution was given therapeutically to patients. In none of these tests was there the slightest reaction. To date, over 11,000 transfusions have been given with this filter at Harper Hospital under our supervision, and for nearly two years this filter has been standard equipment in four other Detroit hospitals. We believe it has proved altogether efficient and free from any technical difficulties. Being entirely pyrogen free, disposable and inexpensive, it has been by far the best solution to blood filtration which we have had.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

MERCOCRESOLS.—Mercresin-Upjohn.—A mixture consisting of equal parts by weight of secondary amyltricresol, $CH_3(OH)C_6H_3CH(CH_3)C_3H_7$, and *ortho*-hydroxyphenylmercuric chloride, *o*-HOC_6H_4HgCl. Mercocresols is used in the form of a tincture containing secondary amyltricresol 0.1 per cent and orthohydroxyphenylmercuric chloride 0.1 per cent dissolved in a solution containing 10 per cent acetone, 50 per cent alcohol, and water.

Actions and Uses.—Mercocresols, the combination of cresol derivatives and an organic mercury compound as previously defined possesses germicidal, fungicidal and bacteriostatic properties peculiar to its two component parts. The actions of its two constituents supplement each other, so that the mixture is approximately twice as germicidal for Staphylococcus aureus as the component cresol derivatives alone and seven to ten times as germicidal as the mercury compound alone. The estimated total effect should not be construed to be of that same order for all pathogenic bacteria and should be understood to represent a summation of activity rather than synergistic action of the two components. Its use as a germicide is subject to some of the same shortcomings as ordinary tricresols and organic mercurial antiseptics, particularly with respect to its inability to destroy bacterial spores

Mercocresols is useful in the form of the tincture for external application as an antiseptic for minor superficial wounds or infections and as a prophylactic disinfectant for surgical preparation of the intact skin. Subject to dilutions variously indicated in the paragraph on dosage it is also useful for topical application to mucous membranes and for irrigation of certain body cavities and deep infected wounds.

The toxicity of mercocresols is principally that of the organic mercurial component. Mercocresols is compatible with both acids and alkalies and does not precipitate with the chlorides of the body fluids.

Dosage.—Mercocresols is applied topically in the form of the undiluted tincture (containing secondary amyltricresol 1:1,000 and orthohydroxyphenylmercuric chloride 1:1,000) to all superficial wounds and for surgical preparation of the intact skin. It may be similarly applied to the ear, nose and throat, but dilutions of from 1:5 to 1:20 should be used for irrigation or wet packs applied to these surfaces. In general, from 1:2 to 1:20 dilutions are used for topical application, irrigation or tamponage of inflamed mucous membranes, depending on the site and method employed. For irrigation of deep infected wounds or abscesses dilutions of from 1:5 to 1:10 are recommended; for irrigation, instillations or lavage of the bladder and urethra from 1:10 to 1:20 dilutions should be used. Dilutions of from 1:10 to 1:20 are also employed for instillation in the eye

Tests and Standards.—

Secondary amyltricresol ($C_{12}H_{18}O$ — F W. 178.26) is a mixture of isomeric secondary-amyl cresols obtained by the reaction of cresol and sec-amyl alcohol It appears as a yellowish liquid, which darkens on exposure to light and air and possesses a phenol-like odor It is miscible with the common organic solvents (acetone, alcohol, benzene, chloroform and ether), soluble in solutions of fixed alkalis forming a cloudy solution; slightly soluble in water, and soluble in an aqueous solution of 10 per cent acetone and 50 per cent alcohol, from which it does not precipitate on addition of water. A saturated aqueous solution is neutral or slightly acid to litmus. It gives no color reaction with ferric chloride T.S At a pressure of 5 mm. of mercury not less than 95 per cent distils between 115 and 130 C. The refractive index is 1.5140 to 1.5190 at 25 C. The specific gravity is 0.95 to 0.98 at 25 C.

Orthohydroxyphenylmercuric chloride (C_6H_5OHgCl.—M. W. 329.26) is a white or slightly buff colored, crystalline powder, soluble in alcohol, ether, acetone, mineral acids and in solutions of fixed alkalis, very slightly soluble in water, and soluble in an aqueous solution of 10 per cent acetone and 50 per cent alcohol It melts at 147 to 151 C. The saturated aqueous solution is slightly acid to litmus. A 0.1 per cent solution in diluted nitric acid yields the following qualitative reactions. the addition of ammonium sulfide T.S. gives no precipitate within five minutes, but on warming the solution over a steam bath a black precipitate is formed, on warming with silver nitrate T.S. it yields a white precipitate soluble in excess strong ammonia solution, when treated with an excess of sodium hydroxide T.S. it yields no yellow precipitate (mercuric ion) and the color does not darken (mercurous ion)

Orthohydroxyphenylmercuric chloride gives no color reaction with ferric chloride T.S It yields not more than 0.1 per cent of residue on ignition There is no apparent loss of weight on drying in vacuum over phosphorus pentoxide for twenty-four hours The alcohol-insoluble residue does not exceed 2 per cent of the original sample.

Transfer 300 mg. of orthohydroxyphenylmercuric chloride, accurately weighed, to a 250 cc beaker containing 5 cc. of hydrochloric acid and 150 cc of water; heat this on a steam bath until solution is complete. Saturate the warm solution with hydrogen sulfide and allow it to stand until the precipitated mercuric sulfide has settled. Filter on a Gooch crucible and wash with water, alcohol, ether, carbon disulfide and ether in the order listed. Dry in an oven at 100 to 110 C. for one-half hour and finally cool in a desiccator: the weight of mercuric sulfide multiplied by 0.8622 is equivalent to a mercury content of not less than 60.5 per cent or more than 61.6 per cent.

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Tincture Mercresin (Tinted): 60 cc. (Pistol Grip), 118 cc., 473 cc. and 3.785 liter bottles. A tinted solution of mercocresols 0.2 per cent in a mixture of acetone 10 per cent, alcohol 50 per cent and water.

Tincture Mercresin (Stainless): 118 cc., 473 cc. and 3.785 liter bottles. An untinted solution of mercocresols 0.2 per cent in a mixture of acetone 10 per cent, alcohol 50 per cent and water.

AMINOPHYLLINE (See New and Nonofficial Remedies, 1947, p. 305).

The following dosage forms have been accepted:

GOLD LEAF PHARMACAL CO., NEW ROCHELLE, N. Y.

Solution Aminophylline: 0.5 Gm. in 2 cc. and 20 cc. ampuls and 0.25 Gm. in 10 cc. ampuls.

SMITH-DORSEY CO., LINCOLN, NEB.

Suppositories Aminophylline: 0.5 Gm.

DIPHENYLHYDANTOIN SODIUM (See New and Nonofficial Remedies, 1947, p. 400).

The following dosage form has been accepted:

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Diphenylhydantoin Sodium (Powder): 28 Gm., 113 Gm. and 453 Gm. bottles.

DIETHYLSTILBESTROL DIPROPIONATE (See New and Nonofficial Remedies 1947, p. 351).

The following dosage forms have been accepted:

THE BLUE LINE CHEMICAL COMPANY, ST. LOUIS.

Solution Diethylstilbestrol Dipropionate in Oil: 1.0 mg. per cc. in peanut oil, 1 cc. ampuls and 10 cc. vials.

Tablets Diethylstilbestrol Dipropionate: 0.1 mg., 1.0 mg. and 5.0 mg.

EDITORIAL ANNOUNCEMENT

The absence of the compositors from their work continues. This issue of THE JOURNAL has been prepared in part by the use of Vari-Typer machines.

NUTRITIONAL INFERIORITY OF VEGETABLE PROTEINS

Adopting a technic previously used by them for a study of the immunologic depression due to thiamine, riboflavin and vitamin A deficiencies[1], Guggenheim and Beuchler[2] of the Department of Bacteriology, Hebrew University, Jerusalem, placed groups of young rats on well balanced diets containing varying amounts of different animal or vegetable proteins. After keeping the rats on these diets for four weeks, tests for the bactericidal and phagocytic properties of their peritoneal fluids were made, with parallel determinations of their change in body weight. In a typical experiment, four diets containing 18, 9, 6 and 3 per cent casein, respectively, were used. At the end of four weeks each rat was given intra-abdominal injection of 0.5 cc. of a twenty-four hour broth culture of Salmonella typhi murium. Two hours later peritoneal fluid was withdrawn and the number of leukocytes, phagocytes and extracellular and intracellular bacteria per microscopic field was determined. The number of residual bacteria in the peritoneal fluid increased as the casein percentage in the diet decreased. Thus, in rats fed 18 per cent casein, only 17 extracellular and 13 intracellular bacteria were found, a total of 30 bacteria per field. This increased to a total of 159 per field in the rats fed 9 per cent casein and to 236 per field with rats given as little as 6 per cent. With those fed but 3 per cent casein the count was 318 per field.

From these data the investigators concluded that the bactericidal power of the peritoneal fluid is reduced by even a moderate degree of casein deficiency. In severe states of deficiency a significant reduction in phagocytosis was also found. The anti-infectious titer of the peritoneal fluid is roughly parallel with increase in growth. Maximum growth and maximem titer were both recorded with rats fed 18 per cent casein; decreased growth and titer with those fed 9 and 6 per cent; a slight loss of weight and minimum titer with rats fed but 3 per cent casein.

In a second test groups of recently weaned rats were placed on diets in which 9 per cent of five other proteins (eggs, meat, soybean, peanut and maize) were substituted for casein. The results showed that both the growth-promoting power and anti-infectious effect of either 9 per cent egg or meat protein is approximately equal to that of 18 per cent casein. Both egg and meat proteins, therefore, have apparently twice the anti-infectious power of casein. With 9 per cent soybean protein the effects were approximately the same as those with 9 per cent casein. Peanut protein was slightly inferior, giving results equivalent to those of but 6 per cent casein. Maize protein was even poorer, 9 per cent maize protein giving results as low as that of but 3 per cent casein.

These vegetable proteins did not affect both anti-infectious titers equally. Thus the nutritional deficiency caused by a diet containing but 9 per cent peanut protein reduced the phagocytic apparatus more severely than it did the humoral antibody. In contrast rats kept on either egg or meat protein have a low phagocytic index, compensated for by a heightened humoral bactericidal titer.

No theory is as yet suggested to account for the immunologic inferiority of vegetable proteins.

INTERNATIONAL MENTAL HEALTH

The World Congress on "Mental Health and World Citizenship" scheduled for August 1948 in London will discuss (1) problems of world citizenship and good group relationship; (2) the individual and society; (3) family problems and psychologic disturbances; (4) planning for mental health organization, training propaganda, and (5) mental health in industry and industrial relations. Committees and discussion groups have been established composed of psychologists, psychiatrists, sociologists, educators, anthropologists and members of other technical groups in the human sciences. The object of the Congress is to find areas

2. Guggenheim, K., and Buechler, E.: J. Immunol. 58: 133, 1948.

on which scientists from all over the world can agree in defining some of the basic principles of mental and social health. Educational work directed along lines of agreement should then be a reasonable outcome.

Symptoms and signs of lack of mental health in the United States as compiled by Menninger and summarized in THE JOURNAL[1] can be multiplied by the total number of nations. These symptoms of personal insecurity, prejudice, hostility, irrational and irresponsible behavior must reflect themselves to an extent in international relations as these are conducted by persons who bring everything they are into everything they do. The subjective background of personal qualities which now determines political leadership needs to be subjected to critical impartial psychologic study.

The problem of mental health, whether personal, family, community, national or international, appears to revolve about security and responsibility. Repeatedly, however, examples are cited wherein too much security from above has led to irresponsibility in the secured. Security on a personal or national level cannot protect the individual from the mental distresses of international insecurity as expressed by war or threat of war. A moral rebirth in personal responsibility is necessary particularly among those charged with the conduct of international relations.

The increasing numbers of mentally and emotionally disturbed patients in clinics and hospitals are in part a reflection of the present low standards of world mental health. The scientific method itself has in a sense contributed to present conditions of mental health by its relentless exposure of the objective half of truth and only recently recognition of its subjective counterpart.

Evidence of mass insecurity and mental disturbance among hundreds of thousands of our own citizens as a result of mental stresses of the recent war indicates the probable mental hazards of atomic and biologic warfare. Previous to the war psychiatrists attempted to treat persons for abnormal reactions to normal situations. During the war essentially normal reactions to highly abnormal situations were met. William Menninger[2] emphasizes the continuation of these stresses today: "The condition of the world now places many people in a continuously abnormal situation to which they are reacting normally even though by all previous standards their behaviour is pathological. In such a turbulent world one might legitimately ask, What is a normal reaction?'

Fortunately the present threat to mental health appears concurrently with the development of the sciences of psychiatry, psychology and sociology, to the point where preventive advice of value is available and applicable in mass situations.

Current Comment

CANCER IN DIABETIC PERSONS

Review of the literature having indicated an apparent association between cancer and diabetes mellitus, Jacobson[1] made a statistical study to determine this point. Recent reports by Marble,[2] Ellinger and Landsman[3] were in definite agreement that clinically physicians are concerned with diabetic patients in whom cancer later develops rather than a group of patients with malignant disease in whom diabetes develops. As relative duration of diabetes is much longer, this appears to be a reasonable conclusion. The subject was attacked in two phases—mortality data from the "universe of dead persons" and morbidity data from the "universe of living persons." Mortality data for analysis were relatively easy to obtain. Of all deaths in the United States in 1940, 11.17 per cent were attributed to cancer. This factor is changed in the "universe of living persons," in that cancer is reported to have caused the deaths of 0.12 per cent of the population of the United States in 1940. From a special tabulation of associated causes of death in the United States in 1940 it was noted that cancer is reported in 11.6 per cent of nondiabetic persons and only 4 per cent of those with diabetes. Cancer of the digestive organs and the peritoneum, including the pancreas, is reported twice as frequently for the nondiabetic group. This does not indicate dissociation but is probably due to the influence of incomplete reporting of associated diagnoses on death certificates, although such effect obviously cannot be accurately demonstrated. Special mortality data for New York city report cancer less frequently among diabetic persons than among nondiabetic persons. This again does not show true dissociation. A classic former example of such apparent dissociation was obtained from necropsy data on association between diagnoses of of future or new members of the professions and advice given to them individually and collectively reflect a true picture of the importance, responsibilities and publicly controlled capacities of government services to accomplish their prescribed missions and objectives; *(d)* that advice and support directly to the chief medical officers of the services is of continuing and positive nature leading to feasible and realizable improvements of the services; *(e)* that adequate indexes and factors applicable to all medical and related functions essential for the civil population are rapidly developed in such form as to permit comparison with military logistic data, and that suggestions toward improvements in the latter be offered with a view to obtaining universally comparable data, and *(f)* that all of the foregoing be based on profound observance of need for balancing all medical resources with all medical needs in a national emergency while preserving maximum personal liberty and individual freedom of action compatible with the good of the whole population established within an ordered pattern.

REAR ADMIRAL M. D. WILLCUTTS (MC), U.S. Navy: The Department of the Army informs me that its authority to order reserves to active duty has expired. They can request reserve officers and enlisted men to volunteer, but cannot force them to serve. An act of Congress states that they cannot be called to active duty for more than fifteen days a year against their will except in time of national emergency, declared by Congress itself. Nor can the Navy call their reserves to active duty without an order from the President or Congress. The act of Congress authorizing the Naval Reserve states that these officers and men can be ordered to active duty in time of war or when the President considers there is a national emergency. The majority of naval reserve officers went into inactive status when they left the service, retaining their commissions, very few resigning. During a national emergency the President has the power to call the National Guard into federal service; this does not need the approval of Congress. The National Guard cannot be sent outside the United States unless the President obtains specific approval from Congress or unless individuals in the National Guard volunteer for overseas service.

Should the President proclaim a national emergency, the consensus is that the Army, Navy and Air Force could hold their active enlisted men beyond the expiration of their present tours of duty. Otherwise, unless they voluntarily signed up for further service, they would have to be released at the end of their enlistments.

The three services have a total authorized strength of 1,732,000 officers and men. The Army has an authorized strength of 669,000 officers and enlisted personnel; the Navy is authorized 500,000 men plus 52,000 officers; the Marine Corps, 100,000 men and 10,000 officers, and the Air Force, 337,000 enlisted men and 61,000 officers. The President has stated that this authorized strength must be reestablished and has recommended reenactment of the Selective Service Act. The Secretary of Defense and the military chiefs urge that the authorized strength for the Armed Forces be increased to 1,734,000 with provision for an additional 181,000 should legislation for universal military training be enacted, for a grand total of 1,915,000.

The Navy Medical Corps is seriously involved. The authorized strength of medical officers, based on full Navy strength, is 4,315. Budgetary limitations have reduced the active strength of the Navy to a level requiring 3,130 medical officers in order to fill essential billets. There are, operative census, 2,856. Of this number, 1,436 are reserve medical officers, 500 of them V-12 men whose two year obligated service is expiring and who will thus be released to inactive reserve status within the next sixty days. A remaining larger group is due to be released in July 1949.

The Bureau of Medicine and Surgery would like considered opinion on whether these excellent young medical officers with two years' naval training should now be released. In view of their country's need, should their release be deferred at least until new medical classes may be ordered up and trained or the older men be given an opportunity to redon their uniforms? Just as hostilities ceased in Japan atomic energy was introduced, harnessed as a high explosive weapon capable of mass destruction. At Hiroshima and Nagasaki I was deeply impressed with the medical personnel losses. Of three hundred resident physicians in Hiroshima, two hundred and sixty were killed or severely injured. Seventy-five per cent of the total nurses, orderlies and trained first-aid workers were immediately wiped out. Not one hospital was left in condition to shelter patients; practically all medical equipment was destroyed. The bombs at Hiroshima and Nagasaki are now known as baby bombs. Scientists developing the atomic bombs claim that bombs one thousand times more powerful are now possible. These bombs may cause death 500 miles beyond the actual target area. It has been estimated that a single bomb per city, dropped over twenty of our great cities, could cause the death of 20,000,000 persons.

Modern war will mean an immediate all-out national effort. Physical standards for recruitment may need to be modified, for every ounce of manpower will be necessary. Those with chronic disorders, even of the psychiatric type, must fight or work. With the advent of specialized weapons a constant prewar status must be maintained, a defense against a treacherous enemy's first blow.

The National Security Act of 1947 declared that it is the "intent of Congress to provide a comprehensive program for the future security of the United States, to provide for the establishment of integrated policies and procedures for the departments, agencies and functions of the government relating to the national security.'' Two high level agencies were provided for the purpose of " coordination for national security," namely, the National Security Council and the National Security Resources Board.

The following recommendations have been made: *(a)* that a National Emergency Medical Council be established as a continuing function of the national government; *(b)* that such a council be an agency of the National Security Resources Board, to which the council would be directly responsible; *(c)* that the council be comprised of representatives from the several recognized national medical and allied organizations and associations; *(d)* that the members of the council function on a part time basis; *(e)* that the council be charged, under the National Security Resources Board, with the consideration of policies and the preparation and maintenance of plans for use in the event of acute national emergency for: (1) mobilization and most effective utilization of the total medical and allied resources of the Nation; (2) the allocation of medical and related personnel to best meet the civil and military needs; (3) coordination of provisions for mutual medical aid between communities and municipalities, and (4) coordination of civilian and military medical services on a national scale under the various wartime situations which may be encountered; *(f)* that the foregoing, or similar action designed toward the same end, be initiated without delay to achieve the primary objective of assuring the nation's readiness to provide, with the limited total medical resources which will be available, the best possible over-all medical coverage under all contingencies of an actual wartime national emergency.

The medical personnel of the Armed Forces are being trained in the medical aspects of new and powerful weapons. Civil medicine must do likewise. Medical schools and postgraduate medical courses should stress these subjects, so that every American physician may be alerted to these new war hazards.

Washington Letter

(From a Special Correspondent)

June 25, 1948.

President Signs Bill Authorizing Federal Heart Research

President Truman signed the bill authorizing the U. S. Public Health Service to support research on diseases of the heart. Establishment within the health service of a National Heart Institute, to aid cardiac disease research through grants, fellowships and similar means, is provided. As the bill carried no funds, Federal Security Administrator Oscar R. Ewing and Dr. Leonard Scheele, Surgeon General of the health service, asked a Senate appropriations subcommittee to include $6,730,000 in the last big deficiency bill. Congress had already appropriated $2,644,088 for studies of cardiac disease in the next fiscal year, but the extra funds were sought to implement the new law setting up the National Heart Institute.

Condemns Practice of Attaching Riders To Appropriations Bills

The electorate will decide next November when the vote is taken for the presidency on who wins the end-of-session row between President Truman and the Republican-controlled Congress; yet the Chief Executive aroused considerable favorable comment in the Capitol for criticizing the practice of attaching legislative riders to appropriations bills. Observers say that the President acted wisely in returning the billion dollar Social Security bill, which provides funds for this federal agency, because of the riders. Congress, in turn, was accused of "politics" in overriding his veto of this legislative item.

Admiral Solberg Nominated Navy Research Chief

President Truman nominated Rear Admiral Thorvald A. Solberg, aged 52, to be the U.S. Navy's new chief of research. He is an expert on atomic energy. Named to a three year term, he succeeds Admiral Paul F. Lee, who is retiring soon. Admiral Solberg directed preparation on the ships used as targets for atomic bomb tests at Bikini Atoll in the Pacific. He later supervised inspections to determine effects of the bombs. He has, since 1936, served as Navy member of the Military Liaison Committee of the U.S. Atomic Energy Commission. He is a native of Madison, Wis., and his home is in Sand Point, Idaho.

Committee Investigates Civil Service "Physical Disability" Firings

The House Civil Service Committee is investigating charges against various federal departments and agencies of alleged truthless firings of employees on false charges of "physical disability." Committee staff members charge that government workers, apparently in good health, have been summarily dismissed on disability grounds. Committee Chairman Rees is directing the probe.

Dr. Detlev W. Bronk Elected to Royal Society

Washington friends have tendered congratulations to Dr. Detlev W. Bronk on his election to the Royal Society of London. He is foreign secretary of the National Academy of Sciences, chairman of the National Research Council and director of the Johnson Research Foundation, University of Pennsylvania.

Medical Legislation

Louisiana

Bills Introduced.—H. 19 proposes the creation of a state medical laboratory to make such medical tests, examinations, experiments or other work as may be assigned to it by the director of the Louisiana State Department of Health. H 58 proposes the creation of a state hospital board to contract or enter into agreements with privately owned hospitals and other institutions for the care and treatment of indigent or destitute sick persons. At least two members of said board must be capable and reputable physicians engaged in the general practice of medicine in the state. According to the proposal the care to be given to indigents should include necessary outpatient care and treatment after hospitalization as well as proper dental, medical, surgical and other treatment. H. 61 proposes the organization and establishment of a state tuberculosis commission to provide for the suppression of tuberculosis within the state and means for the isolation, care, cure and treatment of persons suffering therefrom. H. 271 proposes the creation of a state board of chiropractic examiners and defines chiropractic as the art and science of locating and adjusting the articulations of the spinal column and adjacent tissue. H. 285 proposes to authorize associations created to furnish hospital care to provide also for the furnishing of surgical and medical benefits. H. 287 proposes an appropriation to the state hospital board for conducting a hospital survey and construction program and a mental health program in the state. H. 305 proposes that all persons making application for a license to be married must first be examined as to the existence or nonexistence of a venereal disease, the examination to include a recognized blood test for syphilis, such examination being made by a physician duly licensed to practice in the state. The proposal would further provide that the required blood test for syphilis may be made in any laboratory, public or private, which is generally recognized by the medical profession of the state. H. 315 proposes an appropriation of $300,000 to the Louisiana State Board of Health to be used to match federal and local funds to provide for constructing and equipping public health centers, including administrative offices, laboratories and clinics. H. 430 proposes, among other things, that corporations which issue promises to members to provide for the attendance of a physician and surgeon and to furnish hospitalization, drugs, etc in the event of sickness or physical disability shall be deemed to be engaged in the business of service insurance on the stipulated premium, cooperative or assessment plan. H. 457 proposes to authorize domestic industrial insurers, domestic service insurers and domestic life, health and accident insurers on the cooperative or assessment plan to issue policies providing for ambulance benefits. S. 13 proposes the creation of a Louisiana Hospital Commission for the survey of the need for additional hospital facilities and the development and administration of a hospital planning and construction program. The proposal would require the appointment of a state advisory council and would designate the Commission as the sole agency to institute and conduct a mental health program in the state in compliance with the provisions of the National Mental Health Act and to accept and expend federal funds in accordance with the requirements of any federal hospital survey and construction act. S. 155 proposes to prohibit the sale of potassium bromate and all other heavy metal bromates except on a prescription of a duly licensed medical doctor. S. 178 proposes to require manufacturers of preparations used for hair waving purposes to print certain warning material on the label of each container.

GOVERNMENT SERVICES

ARMY

KOREAN INTERNS IN FOUR ARMY HOSPITALS

Following examinations held in May, sixteen Korean doctors, graduates of recognized hospitals, will soon begin serving internships at four Army hospitals maintained by the American occupation forces in Korea, Only doctors with a knowledge of English were eligible for these competitive examinations. Of the thirty-eight applicants, four are to be each assigned to the 34th General Hospital, Seoul; 382nd Station Hospital, Camp Ascom; 377th Station Hospital, Seoul, and the 71st Station Hospital at Pusan, where they will be given a one year rotating service. Among those cooperating in furthering this new step was Dr. John D. Bigger, a graduate of the University of Kansas and a missionary who has practiced Medicine in Korea for thirty-seven years. Dr. Bigger was a Japanese prisoner for six months at the start of the war, then went to Manila to engage in relief work, coming back to Korea in 1945 to become a civilian employee of the Department of the Army.

Koreans taking the examinations for interns in U. S. Army Hospitals at Seoul. Standing from left to right are Dr. C. C. Choi, deputy director, Department of Public Health and Welfare and Dr. John D. Begger.

PATHOLOGIST PROMOTED TO BRIGADIER GENERAL

The Senate on April 26 confirmed the appointment of Col. Raymond O. Dart, director, Army Institute of Pathology, as a permanent brigadier general in the Medical Corps of the Army. General Dart, a native of Kansas, is a graduate of the University of Kansas and of Rush Medical College; he interned at the Presbyterian Hospital, Chicago, and since entering the Army in 1917 has spent most of his service in the field of pathology. He served in Europe in World War 1 and for a time was commandant of the 105th General Hospital in World War II, surgeon of the Brisbane, Australia, base and New Guinea advanced section, and deputy chief surgeon in the Pacific Area. He has been awarded the Legion of Merit and the Bronze Star.

GRADUATE COURSE IN PHOTOMICROGRAPHY

The Army Institute of Pathology announces that preliminary arrangements have been made by the Army Medical Illustration Service and the United States Department of Agriculture to start a postgraduate course in photomicrography at the Institute of Pathology Photographic Laboratory, 7th Street and Independence Ave., Washington, D. C. The opening date probably will be the first week in September.

PERSONALS

Col. J E. Ash, Scientific Director, American Registry of Pathology, with offices at the Army Institute of Pathology, conducted a three day postgraduate seminar on "Tumors of the Genital Urinary Tract" at the University of Texas, Galveston, in May.

Dr. Hans F. Smetana of the Army Institute of Pathology discussed granulomatous reactions in regional enteritis before the Washington, D. C., Society of Pathologists, May 25.

Col. William A. Smith, recently post surgeon at Fort Jackson, South Carolina, who retired from active service May 31, has accepted a position with the North Carolina board of health's tuberculosis division at Raleigh.

NAVY

VIRUS PRODUCED IN ABSENCE OF HOST CELLS FOR FIRST TIME

The Surgeon General has announced the first successful experiments on the production of a virus in the absence of the host cells (bacteria). The experimental work was described by Dr. Albert P. Krueger, scientific director, Office of Naval Research, Task V on Airborne Infections at the University of California. Dr. Krueger, a reserve captain in the Navy Medical Department, was awarded the Legion of Merit for outstanding work during the war as commanding officer of the Navy's Research Unit No. 1 at Berkeley, Calif. Scientists have been trying for years to make a virus reproduce apart from living cells but, the announcement states, it was never done until Dr. Krueger's recent work. This discovery opens up a new aspect of virus research. The particular virus (phage) in question, which was first discovered in 1915, is a highly complex nucleoprotein found in soil, polluted rivers and within the human body. Dr. Krueger began his experiments twenty years ago and attempts to extract the cellular substance, which rapidly reacts with phage to form more phage, always ended in failure until early in 1948. This research project, an account of which will appear in the July *United States Naval Medical Bulletin*, was supported by the Office of Navy Research and the Bureau of Medicine and Surgery.

Safety in Operating Rooms

Lieut. A. W. Kenny, safety officer, returned May 15 from a three week safety survey of naval hospitals in Corpus Christi and Houston, Texas, and Pensacola, Key West and Jacksonville, Fla. He was appointed to serve on a committee to study the hazards from explosions of anesthetics in operating rooms. The committee comprised representatives from the National Bureau of Standards, the Public Health Service, the Veterans Administration, Navy Department, Bureau of Mines and the Public Buildings Administration.

NEW MEDICAL OFFICERS

The following reserve officers who have been on active duty have accepted appointments in the regular Navy Medical Corps: Lieuts. (jg) John B. Miller of Fairmont, Minn; Lewis G. Richards Jr., of Roanoke, Va.; Robert E. Rowand of Swarthmore, Pa.; Robert W. Sharp Jr., of Grenada, Miss., and Arthur J. Wilets of Burlington, Wis.

The following recent graduates of medical schools have accepted appointments as lieutenants (jg), MC, in the Regular Navy and will serve their internships as follows:

John J. Dempsey, Upper Darby, Pa., to the Naval Hospital, Bethesda, Md.

Robert F. Dykhuizen, Indianapolis, to the Naval Hospital, Long Beach, Calif.

William A. Fisher, Lykens, Pa., to the Naval Hospital, Bethesda, Md.

Rudolph H. Hand, Greenville, S.C., to the Naval Hospital, Portsmouth, Va.

Clarence A. Harvey, Santa Ana, Calif., Naval Hospital, Oakland, Calif.

Samuel W. Johnson Jr., Norfolk, Va., Naval Hospital, Philadelphia.

James S. Ketcham, Rossville, Ind., Naval Hospital, San Diego, Calif.

Ernest W. Klatte, Indianapolis, Naval Hospital, Long Beach, Calif.

Bennie J. Massey, Palatka, Fla., Naval Hospital, Jacksonville, Fla.

Robert F. Neal, Elmwood, Tenn., Naval Hospital, Bethesda, Md.

Vincent P. Russo, Bronx, N.Y., Naval Hospital, St. Albans, L.I., N.Y.

Delmer J. Pascoe, Glendale, Calif., Naval Hospital, Long Beach, Calif.

Arthur C. Smid, Omaha, Neb., Naval Hospital, Great Lakes, Ill.

Henry A. Sparks, Los Angeles, Naval Hospital, Long Beach, Calif.

Robert E. Suer, Cincinnati, Naval Hospital, Long Beach, Calif.

Edward A. Thompson, Marshall, Va., Naval Hospital, Bethesda, Md.

Robert W. Watson Jr., Burlingame, Calif., Naval Hospital, Chelsea, Mass.

PERSONALS

Rear Admiral Lamont Pugh has been elected a member of the Executive Committee of the National Board of Medical Examiners.

Capt. Charles G. McCormack and Comdr. Ben Hollander, San Francisco, both on the retired list, are being recalled to active duty and will be assigned respectively to the Bureau of Medicine and Surgery, Washington, D. C., and the Mare Island Naval Shipyard, Vallejo, Calif.

Comdr. Charles A. Castle, MCR, of Watertown, S.D., and Lieut. (jg) Lynn E. Anthony, MCR, of Macon, Ga., are returning to active reserve status for a period of one year and will be assigned respectively to the Naval Hospital, Great Lakes, Ill., and the Naval Hospital, Dublin, Ga.

Capt. Joseph L. Schwartz, recently in command of the Naval Hospital, Brooklyn, N. Y., has been transferred to the Bureau of Medicine and Surgery, Washington, D. C., as editor of the *Naval Medical Bulletin*.

Rear Admiral John P. Owen (MC), who retired from active duty May 1 at his own request after thirty-one years of active service, has accepted a position as medical advisor to the Superior Court of San Francisco and San Francisco County.

Ensign Yoshiko Tanigawa of Minneapolis is the first nurse of Japanese ancestry to be commissioned in the Nurse Corps of the U.S.Navy, having been sworn into service March 22. Ensign Tanigawa graduated from the Nurses Training School at St. Barnabas Hospital, Minneapolis.

Capt. G. N. Raines, head, Neuropsychiatric Department, Naval Hospital, Bethesda, Md., has been recommended for additional psychoanalytic training at the Washington School of Psychiatry. Capt. Edward P. Kunkel, executive officer, Naval Hospital, San Diego, Calif., has been nominated for duty as medical officer in command of the Naval Medical Center, Guam, Marianas Islands.

VETERANS ADMINISTRATION

DR. MORRISON APPOINTED CHIEF CONSULTANT IN SURGERY

Dr. Paul B. Magnuson, medical director of the Veterans Administration, announces the appointment of Dr. William R. Morrison, Boston, as chief consultant in surgery. Dr. Morrison, who is one of the founders of the American Board of Surgery, recently completed a nationwide tour of veterans' hospitals; he will devote a major portion of his time to the surgical consultant's work. He is a graduate of Harvard Medical School, served in France in both World Wars and for many years has been associate chief examiner in surgery for the National Board of Medical Examiners at Boston and a teacher of anatomy and surgery at Harvard, Tufts College Medical School and Boston University School of Medicine.

SYPHILIS RECORDS

The chief medical director of the Veterans Administration, Dr. Paul B. Magnuson, writes that the Veterans Administration has in its custody the syphilis records of Army personnel who were treated for this disease while in active service and in many cases can procure data from the syphilis records of other than Army personnel. Résumés of these records are available to physicians who are treating such veterans, providing the veteran himself authorizes release of the data. Requests for such a résumé, accompanied by authorization for its release dated and signed by the veteran, should be addressed to the Dermatology and Syphilology Section, Veterans Administration, Munitions Building, Washington 25, D.C. It is important that the veteran's serial number and his date of enlistment and discharge, rank and organization be included.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Cyclotron Begins Operation.—*The cyclotron at the* University of California, Los Angeles campus, began operation early in June. It has been moved from the Berkeley campus and reassembled with double its original capacity. The cyclotron will be used to produce radioactive isotopes for medical research and for experiments in nuclear chemistry.

Personal.—Dr. John C. Ruddock, Los Angeles, reported to the Bureau of Medicine and Surgery, U. S. Navy, Washington, D.C., for ten day's temporary duty during June with the Naval Reserve Policy Board. Dr. Ruddock, a Captain in the Naval Reserve, was Chief of Medicine at the Naval Hospital, San Diego, during the war.

COLORADO

Dr. Sudan Heads Division of General Practice.—The University of Colorado Medical Center, Denver, will inaugurate for the September term its division of general practice in the department of general medicine at the medical school. Dr. Archie C. Sudan, Denver, first winner of the American Medical Association general practitioner award, will head the new division on a voluntary basis, and will be assistant professor of general practice. The division of general practice will screen all admissions both to the Denver General and the Colorado General Hospital. New clinic patients will get a thorough uniform general examination by general practice personnel on admission.

CONNECTICUT

Cooperative Project on Lobotomy.—The Connecticut State Hospital at Middletown, the Fairfield State Hospital, Newtown, The Hartford Institute of Living and the Yale University School of Medicine, department of psychiatry, are making a study of 200 patients who have been subjected to prefrontal lobotomy as a means of treatment of mental illness. This program has been called the Connecticut Cooperative Project on Lobotomy. Dr. Frederick C. Redlich, assistant professor of psychiatry at Yale, stated in a recent broadcast that of the 200 patients, all of whom might have been considered hopeless cases, 8 per cent were free of symptoms a year after the operation; one fifth of the number were able to hold jobs and one half of them could be discharged from institutions. Only 10 per cent were unimproved or got worse. The pioneer experimental work in developing the operation, he said, was done at Yale by Dr. John F. Fulton, professor of physiology, and his associate, Carlyle F. Jacobsen, Ph.D. Later Dr. Egas Moniz of Lisbon, Portugal, developed technics for performing the operation on human beings. Since then several thousand Americans have undergone lobotomies in psychiatric centers in this country.

Most patients subjected to lobotomy at Yale have severe schizophrenia and have not reacted favorably to psychotherapy and shock treatment and are persons for whom there seems no hope by any other therapeutic procedure. We operate, Dr. Redlich said, also on patients with severe and chronic depression who do not react to other procedures and occasionally on patients with extreme compulsive-obsessive reactions. He did not credit the favorable results solely to the operation, as every patient on whom the operation has been done needs psychotherapy and the help of a social worker to adjust, and often the quality of these measures determine to a large degree how good the adjustment of the patient is going to be.

FLORIDA

Meeting of Blood Banks.—At the second annual meeting of the Florida Association of Blood Banks in Miami, May 7-8, papers were presented on the Rh and Hr factors by Drs. Alexander S. Wiener, Brooklyn, Philip Levine, Newark, N. J., Ernest Witebsky, Buffalo, and Louis K. Diamond, Boston. Florida's blood bank organization differs from some other state programs in that there is no central control, but there is uniformity of technic and reciprocity among the banks. Four central banks have been organized with others in the process of organization, as well as a number of sub-banks, which will operate under the supervision of the central banks. The next annual meeting will be in Tampa in February 1949.

IDAHO

State Meeting at Sun Valley.—The Idaho State Medical Association will hold its annual meeting July 6-8 in Sun Valley with headquarters at the Challenger Inn and under the presidency of Dr. Albert B. Pappenhagen, Orofino. The following members of the faculty of the University of Minnesota Medical School, Minneapolis, will present the scientific program: Dr. Owen H. Wangensteen, professor of surgery; Dr. Cecil J. Watson, professor of medicine; Dr. Leonard A. Lang, chief of obstetrics and gynecology, Minneapolis General Hospital; Dr. Donald W. Hastings, professor of psychiatry and neurology; Dr. Edward P. Burch, clinical assistant professor of ophthalmology. Round table discussion groups for luncheon on Tuesday, Wednesday and Thursday have been arranged with one of the guest speakers presiding at each table. The annual banquet will be held July 7 at eight p.m.

ILLINOIS

Health Association Elects Nurse as President.—At the annual conference of the Illinois Public Health Association in Chicago, April 15, Maude B. Carson, chief, division of public health nursing, Illinois State Department of Public Health, succeeded Dr. Edward A. Piszczek, director of the Cook County Health Department, as president. Mr. B. K. Richardson, senior administrative officer of the state department of public health, was named president-elect, and Harold M. Cavins, Ed.D., of the Eastern Illinois State Teachers College, Charleston, was reelected secretary treasurer.

Chicago

Personal.—Dr. Sol R. Rosenthal, assistant professor of bacteriology and public health, University of Illinois, Chicago, left June 12 to attend the First International Congress on BCG Vaccine in Paris June 18-23. He served as vice president of a section on human vaccination.

Visiting Professor.—Dr. Alexander T.M. Wilson, director of the Tavistock Institute of Human Relations, London, England, will be a member of the summer session faculty of Northwestern University beginning June 28 and will conduct his courses under joint sponsorship of the departments of psychology and sociology of the College of Liberal Arts and of the School of Speech. He will also give several public lectures, one on "Current Problems of Education in England" to be delivered July 15. Dr. Wilson received his medical degree at the University of Glasgow, Scotland, 1940. He is a fellow of the Royal Society of Medicine and is on the staff of the Middlesex Hospital in London.

MASSACHUSETTS

Hospital Quarantined for Diphtheria.—The State Mental Hospital, Foxboro, was quarantined May 30 after the outbreak of 5 cases of mild diphtheria among the 1,200 patients.

Society News.—At the annual meeting of the Massachusetts Trudeau Society in Boston in April, Dr. Donald S. King, Brookline, was elected president and Dr. Edward J. Welch, Boston, secretary treasurer..

Appoint Professor of Dermatology.-Harvard Medical School and Massachusetts General Hospital are beginning an intensive program of research on skin diseases. The program, financed part by the Rockefeller Foundation, will be based on cooperation between dermatologists and experts in general medicine. To develop this program, Dr. Chester N. Frazier, head of the department of dermatology at the University of Texas Medical Branch, Galveston, has been appointed professor of dermatology at Harvard and chief of the dermatologic service at the Massachusetts General Hospital. He will organize a new department of dermatology at the medical school and will lead the research and clinical program at the Massachusetts General Hospital. Dr. Frazier, a graduate of Indiana University School of Medicine, has spent twenty years in China, teaching at the Peiping Union Medical College, doing research in skin diseases and training Chinese doctors in the treatment of skin diseases and syphilis. He has also taught and practiced at Indiana University and at Johns Hopkins University School of Medicine, Baltimore.

MINNESOTA

O'Brien Memorial Professorship.--The Minnesota Division of the American Cancer Society, Inc., has established a full professorship in cancer research at the University of Minnesota Medical School, Minneapolis, in memory of Dr. William A. O'Brien, president of the division for ten years before his death. A $5,000 fellowship, established by the division three years ago and held at present by Dr. Robert A. Huseby, will be extended to the full professorship.

Newspaper Award to State Society President.—Dr. Archibald E. Cardle, Minneapolis, president of the Minnesota State Medical Association, on June 9 received the *Minneapolis Star and Tribune* Award for leadership in Minnesota. The award consists of a watch pendant inscribed "For Leadership in Minnesota" and a certificate which reads: "In Recognition of Leadership in Minnesota. Whereas A.E. Cardle as President of the Minnesota State Medical Society has given a service to Minnesota that has added to this state's supremacy as a place in which to live and work, has brought additional respect to his organization and has enhanced his own prestige as a citizen, the *Minneapolis Star and Tribune* presents to him this Leadership Award."

MISSISSIPPI

Medical Rural Scholarships.—Scholarship awards have been granted to fourteen prospective Mississippi doctors by the board of medical education. These students agree to return to practice in rural Mississippi. The program, inaugurated in 1946, has granted 129 scholarships thus far.

Child Guidance Service.—The Mississippi State Board of Health announces the expansion of child guidance services with the opening of a clinic in Greenwood. Children and parents will be given aid in handling emotional problems. Referrals may be made by parents, teachers, physicians, public health officials, the Youth Court and social agencies.

NEBRASKA

Research on Iron Compounds.—The University of Nebraska Foundation has received a grant of $4,000 from the Smith-Dorsey Company, pharmaceutical house, for a study to determine the comparative absorption from the intestinal tract of different iron-containing compounds and their efficacy in regeneration of hemoglobin.

State Medical Election.—At the recent meeting of the Nebraska State Medical Association in Lincoln, Dr. James E. M. Thomson, Lincoln, was installed as president, and Dr. Joseph D. McCarthy, Omaha, was chosen president elect. Dr. McCarthy was also elected delegate to the American Medical Association, with Dr. Harold S. Morgan, Lincoln, alternate. Dr. Roy B. Adams, Lincoln, will continue as secretary-treasurer.

NEW JERSEY

Society News.—At the recent meeting of the New Jersey Obstetrical and Gynecological Society Dr. Herschel S. Murphy, Roselle, became president, Dr. George B. German, Camden, was made president-elect, and Dr. Benjamin Daversa, Spring Lake, was elected secretary-treasurer.

Dr. Bergsma Appointed State Health Commissioner.—Dr. Daniel Bergsma, Trenton, on June 1 assumed duties as New Jersey's first state commissioner of health under the 1947 reorganization of the health department. He replaces Dr. J. Lynn Mahaffey, Haddonfield, former state health director who has been acting as health commissioner since the department reorganized last year. Dr. Bergsma has been with the state department since 1938. After service in World War II, he was named deputy, director and last July 1 became public health consultant.

NEW YORK

Dr. Blaisdell Honored.—Five hundred employees and members of the board of visitors of the Rockland State Hospital, Orangeburg, at a dinner May 24 honored Dr. Russell E. Blaisdell, superintendent of the institution since it opened in 1930. He will retire July 1. On the following day one thousand residents gave a dinner for him in Spring Valley. Dr. Blaisdell has served forty-two years with the department of mental hygiene in New York.

Conferences on Diarrhea of the Newborn.-The state medical society and the state department of health are sponsoring one-day institutes on diarrhea of the newborn in each of the eleven state medical society regions outside New York City. The program for each institute includes a discussion of diagnosis and treatment, the epidemiologic basis for the new Regulation 35, simplification of nursery technics and hospital administration in relation to the control of the disease. A question and answer period follows each program.

New York City

Personal.—Dr. George A. Friedman presented a paper on "Military and Civilian Aspects of Reconstructive Surgery" before the Medical Society of the County of Washington April 13 at Granville.

University Appointments.--Dr. Otto Lowenstein, clinical professor of neurology at New York University College of Medicine, has been appointed professor of neurology at Columbia University College of Physicians and Surgeons. Dr. Lowenstein was associated with Bonn University in Germany, where he was head of the department of pathopsychology. From 1931 to 1933 he was a clinical professor of neurology at New York University. Dr. Cushman D. Haagensen, formerly assistant professor of surgery at the university, was recently promoted to associate professor of clinical surgery

Home Nurse Service.—The Visiting Nurse Service of New York, a public health nursing organization which provides skilled home nursing care by the visit and health guidance for families, day nurseries and small industrial plants, last year made more than 348,662 home-nursing visits. All persons receiving nursing care must be under the supervision of a physician. Almost one third of all babies born in Manhattan, the Bronx and Queens received nursing service from the organization, and over 4,000 expectant mothers were taught to prepare for and care for their babies. While $1.75 per visit is charged to those who can afford to pay, about 49 per cent of the visits are to indigent patients. The organization is largely dependent on contributions for carrying on its free services.

OHIO

Model Poliomyelitis Training Center.— The National Foundation for Infantile Paralysis has announced that it has awarded a five year grant of about $100,000 to Western Reserve University School of Medicine, Cleveland, to set up a model poliomyelitis training center for doctors, nurses and physical therapists. The new center, fifth of its kind sponsored by the National Foundation, will be under the direction of Dr. John A. Toomey, professor of clinical pediatrics and contagious diseases at the university, assisted by a staff of experts on poliomyelitis. Training courses will consist of lectures and demonstrations at City Hospital. The first of three ten-day courses for physicians is scheduled to open July 5. Two week courses for nurses and physical therapists, consisting of lectures, demonstrations and practice, begin July 16. Physicians' courses will include study of the psychic factors accompanying infantile paralysis, such as the mental attitudes of the handicapped and the psychologic pattern of the respirator patient; the role played by the orthopedist in relation to the patient with poliomyelitis in the chronic stage, and the special technics of physical therapy and orthopedic nursing. Physical therapy training will cover such topics as hydrotherapy, normal joint motion and stretching, the evaluation of muscle strength and muscle reeducation. Subjects scheduled for the nursing courses are: recognition of muscle tension, application of hot packs, position of the patient in bed, coordination of nursing and physical therapy duties and the special problems in the care of the respirator and the patient with bulbar paralysis. Some of the courses will be available to local students of medicine, and qualified candidates may be sponsored by their "hometown" chapter of the foundation. Application should be made either to Dr. John A. Toomey or to the National Foundation for Infantile Paralysis, 120 Broadway, New York 5.

WEST VIRGINIA

New Bureau of Hospital and Medical Care.—Dr. Joseph A. Markley, formerly of Morgantown, has been named director of the state health department's new bureau of hospital and medical care. A. J. Williamson, Charleston, former administrator of Charleston General hospital, will serve as field representative for the bureau, which has been set up under the provisions of the hospital licensing law, enacted by the legislature in 1947. Dr. Markley organized Health District No. 4 in 1937 with headquarters at Weston, where he remained until 1940; he was then placed in charge of a hospital under the supervision of the U. S. Department of Agriculture in the Florida Everglades. During World War II Dr. Markley served as U. S. Public Health Service regional medical officer; at the end of the war he located at Miami, Fla., where he engaged in general practice.

WISCONSIN

Course in Infantile Paralysis.—Dr. Hart E. Van Riper, medical director, National Foundation for Infantile Paralysis, will open the course in infantile paralysis at the University of Wisconsin Medical School, Madison, June 28, and will address the dinner meeting at the Loraine Hotel that evening. The course in the diagnosis and care of poliomyelitis is being presented by the medical school and the local chapters of the National Foundation for physicians in Wisconsin, through a selected group of specialists.

VIRGINIA

Personal.—Professor Karl Lindner, chief of the Eye Clinic, Vienna, Austria, delivered seven lectures at the Gill Memorial Eye, Ear and Throat Hospital, Roanoke, February 23-25.

Narcotic Violation.—According to the Bureau of Narcotics, Washington, D.C., Dr. Robert S. Fitzgerald, Martinsville, pleaded guilty to violation of the federal narcotic laws in the U.S. District Court at Danville. On February 24 his sentence was suspended, and he was placed on probation for a period of five years.

University Appointment.—Dr. Samuel D. Sturkie, director of health and welfare for the city of Lynchburg, has been appointed associate professor of preventive medicine in the University of Virginia Department of Medicine, Charlottesville, effective July 1, succeeding Dr. Thomas S. Englar, resigned. Dr. Sturkie is a graduate of the University of Georgia School of Medicine, Augusta, and was appointed health officer in 1934 in Alabama after attending Johns Hopkins School of Public Health. He served as health officer with headquarters in Marion from 1941 to May 1943, when he assumed his present post in Lynchburg.

GENERAL

Statistical Bulletin Available.—The *Statistical Bulletin* of the Metropolitan Life Insurance Company, a monthly publication, is available to physicians on request to the Statistical Bureau, Metropolitan Life Insurance Company, One Madison Avenue, New York 10.

Dr. Zentmayer Receives Howe Award.—The Howe Medal of the American Ophthalmological Society for 1948 has been awarded Dr. William Zentmayer, Philadelphia. The medal was first awarded in 1922, and since then it has been given only fifteen times. Ten of the recipients have been distinguished American ophthalmologists and five outstanding foreign ophthalmologists.

Personal.—Basil O'Connor, chairman of the American Red Cross and president of National Foundation for Infantile Paralysis, was last month awarded a gold medal of the National Institute of Social Sciences. Under his guidance, the institute said, the National Foundation "has achieved a high and permanent place in the land, offering new hope for stricken youth to face courageously a brighter future."

Report of the Markle Foundation.—According to the annual report of the John and Mary R. Markle Foundation, $460,000 was appropriated in 1947 as gifts to colleges and universities for research. Thirty-five institutions received grants, the largest being $60,000 to the Committee on Research in Endocrinology of the National Research Council. The appropriations made during the year for medical research were on a terminal basis of a new program under which the foundation is aiding selected young scientists seeking careers in teaching and research in medical schools (THE JOURNAL Sept. 27, page 238).

Plague Infection in Western Rats.—The U. S. Public Health Service reports that on May 4 plague infection was proved in pools of fleas from rats and mice as follows: In Navajo County, Ariz., a pool of 42 fleas from 4 wood rats were trapped April 15 about 1½ miles southeast of Pinetop, in Lincoln County, New Mexico, a pool of 20 fleas from 21 wood rats were trapped April 15 on a road 3 miles east of Capitan; in Kittitas County, Washington, a pool of 180 fleas from 70 field mice were trapped April 14 6 miles east of Kittitas.

Campaign to Reduce Children's Accidents.—A reduction in the number of children's accidents is the objective of an intensive campaign to be launched this fall by the Metropolitan Life Insurance Company with the cooperation of the U. S. Children's Bureau, the American Academy of Pediatrics and the National Safety Council. Accidents are the leading cause of death among children of more than 1 year of age, with death rates per 100,000 population far surpassing those of any other cause. The program is planned to encourage public health, medical, safety organizations and the public to give greater attention to child safety. A 12 page booklet, "Help Your Child to Safety," is addressed to parents and emphasizes ways of combating physical hazards and unsafe practices resulting in injuries to children. The booklet and other source material will be available from the company on request by September 1 for use in local organized child safety programs.

Awards in Internal Medicine.—Dr. Fuller Albright, Harvard Medical School, Boston, was given the Squibb Award for 1948 at the meeting of the Association for the Study of Internal Secretions in Chicago June 18. Dr. Albright was cited for his contributions on functions of the hormones, his investigation of hyperparathyroidism and hypoparathyroidism, renal disorders, diseases of bone and of the adrenal glands. Dr. Carl G. Heller, University of Oregon Medical School, Portland, was given the Ciba Award for 1948 for his contributions to the physiology of reproduction, with particular reference to the diagnosis and treatment of disorders of reproduction in man. To Dr. Ernest M. Brown Jr., of the George S. Cox Medical Research Institute, University of Pennsylvania, Philadelphia, the society awarded the Ayerst, McKenna and Harrison Fellowship. Dr. Brown will work with Dr Francis D. W. Lukens, Philadelphia, on the production of lesions of the islands of Langerhans.

Research in Heart Disease.—The American Foundation for High Blood Pressure is allocating $75,000 to research on hypertension, arteriosclerosis and associated diseases. The foundation has set up a three member allocations board outside the foundation to provide an impartial and neutral body to consider requests. Members of the board are: Dr. Harry Goldblatt, professor of pathology, University of Southern California School of Medicine, Los Angeles; Dr. Thomas Addis, professor of medicine, Stanford University School of Medicine, Stanford University-San Francisco; and Dr. William Dock, professor of medicine, Long Island College of Medicine, Brooklyn. Distribution of funds, the first allocation of the foundation, will be made to medical schools, hospitals or medical centers. Later, funds will be made available for support of postdoctoral fellows carrying on research on a full time basis. Requests to the foundation at 705 Marion Building, Cleveland, Ohio, for funds for research will be solicited without reference to the amount of money now available for allocation. Worthy requests which cannot be supported at present will be considered at the time of later allocations.

Hospital Construction in Southern States.—Thirteen Southern states will receive $33,215,250, provided by the Federal Hospital Survey and Construction Act of 1946, in annual grants in aid, alloted on the basis of population, per capita income and need. According to the May issue of *New South*, state surveys of hospital facilities indicate that the most acute deficiency is in beds for chronic illness, for which nine states have a total of only 1,877 and a need for 36,489.

All Southern states have had their hospital construction plans approved by the Surgeon General. The poorest rural community will be given first chance at federal hospital aid. Projects already begun include: Florida—five general hospitals, two children's chronic disease hospitals and one psychiatric unit; Georgia—eleven projects to provide 645 general beds and 50 additional chronic disease beds; Alabama--seven projects approved and ground broken for the first hospital; Mississippi--by the end of 1947, 67 out of 82 Mississippi counties had full time health departments; construction of fourteen hospitals and seven health centers has been authorized; Oklahoma—fourteen general hospitals, two community clinics two tuberculosis hospitals, one mental hospital and one auxiliary laboratory. South Carolina is devoting about two thirds of the total funds available for the five year period to building of general hospitals, and Louisiana for the first year is allotting 70 per cent to general hospitals, 12 per cent to public health centers and 9 per cent each to tuberculosis and mental hospitals. Alabama, Mississippi and South Carolina have appropriated state funds to supplement federal and local funds for hospital construction, and other states are considering such addition. In Louisiana a statewide system of government-owned hospitals already provides care for about 30 per cent of the entire white population and 50 per cent of the Negro population. Virginia also operates medical care programs for its indigent in which the state supplies funds to local community hospitals on a matching basis. In Texas, a number of highly successful cooperative health centers and hospitals have bden organized in towns of 2,500 population or less.

Marriages

JAMES CLINTON MONTEITH of Nyack, N.Y., to Miss Anita Ross Taylor of Scarsdale, N.Y., March 20.

WILLIAM DULANEY LEWIS JR., Richmond, Va., to Miss Ruby Louise Martin of Roanoke, March 6

WILLIAM EDWARD LAUPUS, Seymour, Ind., to Miss Evelyn Estelle Fike of Ahoskie, N.C., March 6.

JOSEPH HOLLAND BURCHENAL, Noroton, Conn., to Miss Joan Barclay Riley of New York, March 20.

ROY E. MCDONALD, Erie, Pa., to Mrs. Ann Courtenay Bennett of London, England, March 22.

ROBERT S. BEEKMAN to Miss Mary Marckwald, both of New York, April 3.

JOHN PALFREY AYER, Milton, Mass., to Miss Lea Zimmerman in Tucson, Ariz. March 20.

GEORGE R. MCNEAR JR., Scarsdale, N.Y., to Miss Virginia Eleanor Gray in Maplewood, N.J., March 4.

JOHN STEPHEN THOMPSON, Bloomfield, N.J., to Miss Irene Ruth Malcolm in Roselle, May 1.

ROBERT MURRAY CUSHING, New York, to Miss Robin Fersten of Riverdale, N.Y., April 25.

JAY BEVERLY MOSES, Hamilton, N.Y., to Miss Irma Smith of Springfield, Mo., April 22.

Deaths

William Darrach ⊕ Greenwich, Conn., dean emeritus and professor of clinical surgery at the Columbia University College of Physicians and Surgeons in New York, died in the Greenwich Hospital May 24, aged 72. Dr. Darrach was born in Germantown, Pa., March 12, 1876. Following graduation from Columbia University College of Physicians and Surgeons, 1901, he interned at Presbyterian Hospital, where in 1913 he became an associate attending surgeon, and later a visiting attending and consulting surgeon. He served on the faculty of Columbia University as a demonstrator in anatomy, from 1903 until 1909 and an instructor in surgery from 1903 to 1916, when he became professor of clinical surgery. In 1919 he was appointed dean of the medical faculty, serving until he was made dean emeritus in 1930. It was during his administration that the Columbia-Presbyterian Medical Center was erected. In 1928-1929 he was a member of the administrative board of Columbia School of Nursing and from 1919 to 1928 was president of the board of managers of the Sloane Hospital for Women and the Vanderbilt Clinic. During World War I Dr. Darrach was surgical director of the United States Army Base Hospital number 2 and also was on detached service with the British Expeditionary Force in Charge of General Hospital number 1. He remained with the occupation armies until 1919, when he was discharged with the rank of colonel. During World War II Dr. Darrach was civilian consultant in surgery to the Surgeon General, and in 1945 he was chief consultant to the Veterans Administration in New York. He also had been director of education and research at the the Veterans Administration Hospital in the Bronx. Dr. Darrach was a fellow of the American College of Surgeons and a member of its board of governors, a past president of the American Surgical Association, Association of American Medical Colleges and of the Society of Clinical Surgery. He was member of the founders' group of the American Board of Surgery, a member of the American Association of Anatomists, the Société de Chirurgiens de Paris, American Association for the Advancement of Science, New York Academy of Medicine, American Philosophical Society and others. He was a consulting surgeon at the Northern Westchester Hospital in Mount Kisco, N.Y., Greenwich (Conn.) Hospital, Morristown (N.J.) Hospital, Beckman Street Hospital, Willard Parker Hospital and New York Orthopaedic Dispensary and Hospital. From 1929 to 1937 he was a member of the board of trustees of Vassar College in Poughkeepsie. Dr. Darrach received many honarary degrees, including a doctorate of laws from St. Andrews University in St. Andrews, Scotland. For many years he was an associate editor of *Archives of Surgery*.

Frank Newcomer Hoffmeier ⊕ Hagerstown, Md., born in Middletown, Md. Sept. 15, 1876; Hahnemann Medical College and Hospital of Philadelphia, 1903; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc., Southern Medical Association and American College of Radiology; during World War I served overseas with Evacuation Hospital number 17 in Vladivostock, Siberia, as roentgenologist with the rank of Captain; since February 1947 roentgenologist at the Veterans Administration Center in Martinsburg, W. Va.; for many years affiliated with Washington County Hospital; died February 19, aged 71, of coronary occlusion.

William Eager Howard, Dallas, Texas; born in San Antonio, Tex., Feb. 9, 1877; University of Texas School of Medicine, Galveston, 1897; member of the American Medical Association; specialist certified by the American Board of Otolaryngology; one of the founders of the Texas Society of Ophthalmology and Otolaryngology; formerly vice president of the Pan American Medical Association; veteran of the Spanish-American War; on the staffs of St. Paul's Hospital and the Dallas City-County Hospital System; died February 21, aged 71, of angina pectoris.

August William Fredrich Westhoff, Richmond Hill, N.Y.; Bellevue Hospital Medical College, New York, 1891; member of the American Medical Association; fellow of the American College of Physicians; formerly on the faculty of his alma mater; director emeritus of medicine at the Wyckoff Heights Hospital, Brooklyn; served as attending physician and a member of the medical board of the Bethany Deaconess Hospital and as consultant at St. Cecilia Hospital for Women in Brooklyn; died February 21, aged 82, of cerebral hemorrhage.

Ludwig W. Anderson, Atwater, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1904; died February 19, aged 65.

Esther Lydia Boyer ⊕ Missoula, Mont.; University of Wisconsin Medical School, Madison, 1939; interned at the Madison General Hospital in Madison, Wis.; formerly instructor in the department of anatomy at Woman's Medical College of Pennsylvania, Philadelphia, and instructor in surgery and assistant physician in the student health department at the University Hospitals, Columbia, Mo.; member of the Western Montana Clinic; died March 5, aged 45.

Edward Wilbur Burke ⊕ Redlands, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; an Affiliate Fellow of the American Medical Association; affiliated with the Redlands Community Hospital; died March 3, aged 74, of heart block.

Charles F. Byrd, St. Joseph, Mo.; Ensworth Medical College, St. Joseph, 1895; served as county coroner; died February 20, aged 80.

Emmett Davis ⊕ Library, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1911; died March 3, aged 62, of coronary thrombosis.

Frank Judson Edgett, Amityville, N.Y.; Maryland Medical College, Baltimore, 1912; New York Homeopathic Medical College and Flower Hospital, New York, 1916; health officer; served on the staff of the Brunswick Home, where he died February 26, aged 60.

George K. Gordon, Malden, Mass.; Tufts College Medical School, Boston, 1919; served during World War I; died in the Mount Sinai Hospital, New York, March 3, aged 53, of heart disease.

Edwin R. Gould, Buffalo; University of Buffalo School of Medicine, 1900; died March 1, aged 79, of coronary thrombosis.

Joseph E. Gower ⊕ Spearman, Texas; Kansas City (Mo.) College of Medicine and Surgery, 1919; served as county health officer; died in Shattuck, Okla., February 29, aged 71, of acute nephritis.

Theodore F. Hammermeister ⊕ New Ulm, Minn.; University of Minnesota Medical School, Minneapolis, 1915; died February 14, aged 60.

Ralph Bolender Hannah, Georgetown, Ohio; Miami Medical College, Cincinnati, 1896; member of the American Medical Association; president of the Brown County Medical Society; died in Christ Hospital, Cincinnati, February 25, aged 74, of cerebral hemorrhage.

Vincent Valentine Hardeman, San Francisco; College of Physicians and Surgeons of San Francisco, 1918; died February 29, aged 60, of coronary thrombosis.

Gilbert Cole Herndon, San Antonio, Texas; Baylor University College of Medicine, Dallas, 1935, member of the American Medical Association, served during World War II; died February 6, aged 36, of injuries received in an automobile accident.

Gerrit Heusinkveld ⊕ Denver; University of Colorado School of Medicine, Denver, 1920; died February 26, aged 58, of coronary occlusion.

Dorsey Mark Hines ⊕ Auburn, Ind.; Indiana University School of Medicine, Indianapolis, 1909; served overseas during World War I; affiliated with the Sacred Heart Hospital in Garrett, and Sanders General and Dr. Bonnell M Souder Hospitals, died February 25, aged 61, of nephritis.

Oliver Hunt Howe, Cohasset, Mass.; Harvard Medical School, Boston, 1886; member of the American Medical Association; for many years school physician and medical examiner in Cohasset; president and trustee of the Cohasset Free Public Library; past president of the Norfolk South District Medical Society; died March 1, aged 87

Vincent Joseph Irwin Jr. ⊕ Springfield, Mass.; Yale University School of Medicine, New Haven, 1909; member of the American Academy of Ophthalmology and Oto-Laryngology; specialist certified by the American Board of Otolaryngology; served during World War I; died February 26, aged 60. of coronary thrombosis.

George Chauncey Jameson ⊕ Oberlin, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1893; for many years chief of staff at Allen Hospital; one of the founders of the Oberlin Hospital Association; died February 29, aged 82, of complications following pneumonia.

William Leonard Karcher ⊕ Freeport, Ill.; Medico-Chirurgical College of Philadelphia, 1900; past president of the Stephenson County Medical Society; fellow of the American College of Surgeons; affiliated with St. Francis and Evangelical Deaconess hospitals; died March 3, aged 73, of carcinoma of the stomach with metastases of the liver.

Robert James Kennedy, New Rochelle, N. Y.; Temple University School of Medicine, Philadelphia, 1939, on the staff of New Rochelle Hospital; died in Chattanooga, Tenn., February 28, aged 33, of mitral stenosis and rheumatic fever.

Charles Francis Kuhn, Port Townsend, Wash., Long Island College Hospital, Brooklyn, 1883; also a graduate in pharmacy; served as health officer of Port Townsend; formerly surgeon of the United States Army, Alaska Treadwell Mine in Treadwell, Alaska and the Marine Hospital Service, died in St. John's Hospital February 13, aged 87, of cardiovascular renal disease.

Frank Kunz ⊕ Akron, Ohio; Western University Faculty of Medicine, London, Ontario, Canada, 1906; died February 27, aged 65, of coronary occlusion.

Forrest Leroy Leland, South Hadley Falls, Mass.; Tufts College Medical School, Boston, 1908; fellow of the American College of Surgeons; for many years served on the board of health; member of the American Medical Association; died February 26, aged 67, of coronary thrombosis.

Rollo Bertell Lester, Desloge, Mo.; Washington University School of Medicine, St. Louis, 1904; member of the American Medical Association; affiliated with the State Hospital, Nevada, where he died February 14, aged 72, of cerebral hemorrhage.

Henry Lovett, Philadelphia; Jefferson Medical College of Philadelphia; 1888; at one time practiced in Langhorne, Pa. where he was president of the People's National Bank; died in the Friends Hospital February 22, aged 82.

Robert Cooley Maddox ⊕ Rome, Ga.; Atlanta Medical College, 1916; member of the board of education; past president of the Floyd County Medical Society; president elect of the Seventh District Medical Society; a trustee of the Darlington School for Boys and for many years school physician; served during World War I; died February 23, aged 54, of heart disease.

Wasel Maholage Jr., Mahanoy City, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1934; member of the American Medical Association; died in the Hahnemann Hospital, Philadelphia, February 28, aged 39, of pneumonia.

Ernest George Maier ⊕ Philadelphia; Jefferson Medical College, Philadelphia, 1905; assistant professor of gynecology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; for many years affiliated with Physicians and Surgeons Hospital; died March 5, aged 68, of acute nephritis.

Ralph Vernon Moore ⊕ Portland, Ore.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; fellow of the American College of Surgeons; affiliated with the Emanuel Hospital; died in the Fairlawn Hospital February 26, aged 70, of arteriosclerosis.

Oscar James Mullen, Philadelphia; Temple University School of Medicine, Philadelphia, 1906; member of the American Medical Association; died in the American Stomach Hospital February 29, aged 71.

Bernard Joseph Neary, Johnstown, Pa.; University of Louisville (Ky.) Medical Department, 1911; served during World War I; formerly affiliated with the Indian Service; died February 24, aged 72, of arteriosclerotic heart disease with recurrent infarctions.

Edmund J. Overend, Oakland, Calif.; Medical College of the State of South Carolina, Charleston, 1883; Jefferson Medical College of Philadelphia, 1884; past president of the Alameda County Medical Society; died February 24, aged 93, of bronchopneumonia and influenza.

Gustavo Federico Porro, Tampa, Fla.; Universidad de la Habana Facultad de Medicina y Farmacia, Cuba, 1926; died February 29, aged 47, of coronary thrombosis.

Auguste Rhu, Marion, Ohio; Western Reserve University School of Medicine, Cleveland, 1885; member of the American Medical Association, serving in 1912 as a member of its House of Delegates; past president of the Marion Academy of Medicine; formerly secretary of the Ohio State Medical Association; fellow of the American College of Surgeons; died February 27, aged 93.

John D. Rice, Hiawassee, Ga., Atlanta College of Physicians and Surgeons, 1900; died January 23, aged 73.

Alice Lucinda Root, Winthrop, Mass.; Electropathic Institute, Philadelphia, 1876; died February 22, aged 92.

Charles Whitall Root, Ravenswood, W. Va.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1893; died February 25, aged 79, of carcinoma of the liver.

William Grant Ross, Kempton, Ill.; Rush Medical College, Chicago, 1902; died February 25, aged 79, of coronary thrombosis.

Wilson J. Seal, Sneedville, Tenn. (licensed in Tennessee in 1906); died March 1, aged 78, of angina pectoris.

Alfred Marion Shaw ⊕ Chicago; Rush Medical College, Chicago, 1910; died in Presbyterian Hospital February 7, aged 76, of cerebral thrombosis and arteriosclerosis.

Karl Vollmer ⊕ Davenport, Iowa; State University of Iowa College of Medicine, Iowa City, 1892; past president of the Illinois-Iowa Central District Medical Society; past president and secretary of the Scott County Medical Society; for six years a member of the school board; affiliated with Mercy and St. Luke's hospitals; died February 19, aged 78, of hypertensive heart disease.

Arthur Willard Watson, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1880; member of the American Laryngological Association; formerly associated with the staffs of the Jewish, University and Episcopal hospitals; died February 17, aged 89, of bronchopneumonia.

James Henry Wayland, Plainview, Texas; Kentucky School of Medicine, Louisville, 1886; died in February, aged 84.

George Dillard Wells, Los Angeles; Barnes Medical College, St Louis, 1911; member of the American Medical Association; died February 9, aged 62.

Egbert Hayes Wesson, New Albany, Miss.; College of Physicians and Surgeons, Memphis, Tenn., 1911; served during World War I; died in Veterans Administration Hospital, Memphis, Tenn., February 29, aged 58, of heart disease.

Frank Alonzo White ⊕ Childress, Texas; University of Louisville (Ky.) Medical Department, 1904; past president of the Childress-Collingsworth-Donley-Hall Counties Medical Society and of the Panhandle District Medical Society; formerly secretary of the Hopkins County Medical Society; member of the Texas Society of Ophthalmology and Otolaryngology; local physician for the Fort Worth and Denver Railroad; died January 24, aged 76, of coronary occlusion.

KILLED IN ACTION

LIEUT. COL. WILLIS H. DRUMMOND
M.C., A.U.S., 1899-1944

CAPT. JOHN R. MAGRUDER
M.C., A.U.S., 1914-1945

CAPT. JOHN E. EDGE
M.C., A.U.S., 1919-1945

Willis Hinton Drummond ⊕ Lieutenant Colonel, M.C., U.S. Army, Hollywood, Calif.; State University of Iowa College of Medicine, Iowa City, 1924; fellow of the American College of Surgeons; certified by the National Board of Medical Examiners; U.S. Army Medical School in 1931; entered the medical corps of the U.S. Army as a first lieutenant in 1929; went to the Philippines from Walter Reed General Hospital in Washington in 1940 and was serving at the Sternberg General Hospital in Manila when the war broke out; promoted through the various ranks to that of lieutenant colonel; killed in an air attack in the Pacific area Dec. 15, 1944, aged 45, while being transported aboard a Japanese vessel from the Philippine Islands to Japan.

John Robinson Magruder, Baltimore; born in Baltimore May 21, 1914; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1939; interned at the Baltimore City Hospital in Baltimore; interned at the Charity Hospital in New Orleans, where he served a residency; began active duty as a first lieutenant in the medical corps, Army of the United States, in May 1942; assigned to duty at Brooks Field, San Antonio, Texas; after four months was transferred to the 76th Station Hospital, Camp Livingston, La., performing duties of surgeon, and accompanied that unit to the Pacific theater, where he also served with the 22nd Station Hospital and the 97th Portable Surgical Hospital; promoted to captain; died in action on Luzon Island Aug. 22, 1945, aged 34.

John Evans Edge, Bryan, Texas; University of Texas School of Medicine, Galveston, 1943; interned at the Graduate Hospital of the University of Pennsylvania in Philadelphia; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 1, 1944; stationed at Carlisle Barracks, Pa., Ashford General Hospital, White Sulphur Springs, Va., and Camp Barkeley, Texas; assigned to 82nd Medical Battalion of the 12th Armored Division (7th Army ETO); promoted to captain; awarded the Purple Heart and the Meritorious Service Plaque--82nd Medical Battalion; wounded at Bertheim, Germany, April 8, 1945; died at the 11th Evacuation Hospital at Lauda, Germany, April 9, 1945, aged 25, of wounds received in action.

International Congress on Mental Health

Yet another medical international congress is to be held in London. It has unusual importance in that it aims at taking part in international politics and exerting a healing influence on a sick world. In this third International Congress on Mental Health three main bodies are concerned: the International Committee for Mental Hygiene, the International Committee for Child Psychiatry and the International Federation for Medical Psychotherapy. Some forty-five nations intend to take part. At present nearly two hundred working parties spread over the world are actively preparing material for the program. Educators, sociologists, clergymen, anthropologists, psychiatrists, psychologists and others are turning their attention from academic and individual problems to the study of tensions of communities. The main theme, mental health and world citizenship, indicates that at this congress the emphasis is on sick groups and, indeed, on the sick world: the aim is the achievement of sounder mental health. The congress has the full approval of the British government and the active support of the World Health Organization and of UNESCO. The last has made a substantial grant toward bringing representatives from the war-damaged countries, who would otherwise be prevented from attending by currency restrictions and lack of funds. In addition to the considerable general expenses of a large congress, the organizers are endeavoring to raise a sum of at least $40,000 to pay the expenses of more than two hundred of these delegates.

A large number of working parties are now busy, and on the results of their labors the chief speakers of the congress will be chosen. The children's group is to discuss the development of personality and its individual and social aspects with special reference to aggression. The section dealing with treatment will discuss various aspects of guilt. The main conference on mental hygiene, taking mental health and world citizenship as its theme, will spend a full week on such topics as the individual and society, family problems and psychologic disturbances, and mental health in industry and industrial relations. The suggestion that the congress may develop a permanent organization for mental health, and thus try to find some hope for a frightened world, has received the support of the executive secretary.

Priority on Milk For Polyarthritic Patients

Although three years have passed since the end of the war, the British are still subject to confiscatory taxation, food shortages, rationing and numerous controls of production and individual expenditure. Fresh regulations are always being made to meet the difficulties arising when a government tries to control everything. Recently the Minister of Food, on the advice of the Food Rationing Special Diets Advisory Committee, has decided that patients with an active form of polyarthritis associated with a raised sedimentation rate and loss of weight shall be allowed a priority claim on the supply of 1 pint (473 cc.) of liquid milk a day, on the basis of a certificate from their physician. The minister would like to have made milk available to patients with other types of arthritis also, but the supply is not sufficient for this purpose. The previous criteria have been adopted in order to insure that the limited supply available shall go to those whose need is greatest. When a doctor decides to certify a patient as suffering from infective polyarthritis his certificate should contain the following information: (1) a statement that the condition is active, infective polyarthritis; (2) whether there has been loss of weight, and (3) the value of the sedimentation rate and the date the test was done.

Bill To Protect Workers in Radioactive Substances

A short time ago trade union leaders alleged that some workers in radioactive substances had sustained serious injuries, but this has never been confirmed. However, the government has introduced a Radioactive Substances Bill to protect workers and the public against harmful exposure to radiation. The regulations are similar to those which already exist under the Factories Act for the protection of employees in hospitals, laboratories and industrial establishments. Radium, radon and certain irradiating apparatus, principally roentgen ray tubes, are covered. The legislation applies to all places where radioactive substances or irradiating apparatus are manufactured, treated, stored or used. The disposal of radioactive waste will be controlled, and regulations may be made to prevent injuries during transport of these substances. Only medical and dental practitioners or persons working under their direction who hold a license from the Minister of Health will be allowed to use certain apparatus and radioactive substances for the treatment of patients. The supply of such substances to the public in the form of medicines or toilet preparations will be illegal except under the authority of a prescription from a physician.

Tuberculin Control for All

In 1939 the Norwegian Association of Tuberculosis Doctors recommended tuberculin testing and registration of every one up to the age of 30. On the West Coast of Norway Dr. Tobias Gedde-Dahl, recently appointed as secretary-general of the Norwegian National Association against Tuberculosis, has shown that this recommendation can be translated into remarkably effective action. From 1937 onward he has worked as district medical officer in an area with a population of about 6,500. Using the Pirquet test, he kept the negative reactors under subsequent periodic tuberculin control, while the positive reactors were kept under radiologic control. He has now published his results in a 235 page work entitled "Tuberculosis Infection in the Light of Tuberculin Registration:" A twelve page summary in English is a concession to readers who do not know the Norwegian language and to those Norwegians who like their reading condensed. During the observation period 1937-1944 Dr. Gedde-Dahl found that the overwhelming majority of the population in his district was still tuberculin-negative at the age of 15: about 80 per cent of the urban population and about 85 per cent of the rural. Even at the age of 30, about 30 per cent of the men and about 45 per cent of the women had not yet been infected. Hence, the conclusion that tuberculin control must be extended far beyond the age of 30. Another conclusion was that few children are infected in their homes; many sources of infection are to be found outside them. Dr. Gedde-Dahl has found Pirquet testing far more effective than mass roentgenography as the first step in the discovery of new cases, and he prefers to make the latter subservient to the former, roentgenography to be reserved for tuberculin-positive reactors. During the period under review, the percentage of traced cases of progressive pulmonary tuberculosis in his district rose, but the mortality from pulmonary tuberculosis fell in the same period from 10.8 to 5.7 per ten thousand persons and that from all forms of tuberculosis from 13.5 to 6.4.

Scandinavian BCG Crusade in Europe

In a recent radio talk Dr. Galtung Hansen, who is at the head of the tuberculosis service in Norway, outlined the ambitious and stupendous scheme already set in motion for the examination of 50,000,000 children in eleven countries in middle and southern Europe with tuberculin with a view to the negative reactors' being vaccinated with BCG. The credit for the first steps in this scheme belongs to the Danish Red Cross, which began to operate it more than a year ago. With a recent grant of $2,000,000 and the cooperation of international health experts, the scope of this scheme has been enlarged and the participation of Norwegian and Swedish doctors and nurses has been secured. Between two hundred and three hundred teams, each consisting of one doctor and two nurses, are required for the execution of the scheme in the course of a year and a half. The five doctors and ten nurses who have volunteered in Norway for this service are undergoing special preparatory training. Their task and that of their Danish and Swedish colleagues will include the training in this work of other doctors and nurses in the countries visited.

A Statistical Study of Asthma in Norway

During 1946, Dr. Odvar Claussen, attached to Professor Olav Hanssen's staff at the Rikshospital in Oslo, undertook a statistical study which has added to knowledge of asthma. Or perhaps it will be nearer to the truth to say that he has been successful in emphasizing the many gaps in the knowledge of this disease. By securing the cooperation of eighty-six of the three hundred and seventy-seven District Medical Officers of Health in Norway he has been able to show that there were 1,190 asthmatic persons among the 295,356 inhabitants of the eighty-six districts studied. From these figures he concludes that there are at least 12,000 persons with asthma in the whole of Norway, whose population numbers about 3,000,000. Like other observers, Claussen found male patients in the majority (58.2 per cent), but he ventured on no explanation of this sex difference. In 47 per cent of the women the asthma began after the age of 30, and in 26 per cent after the age of 40. The corresponding figures for men were 41 and 24 per cent, respectively. In the first decade of life there were only 34 girls to every 66 boys, and in the second decade boys were still more in the majority (69 per cent). In as many as 50 cases the asthma had lasted for more than forty-five years. The average weight of both male and female patients was a trifle below normal. No great difference could be found in the frequency of asthma in coastal and inland districts, and Claussen could find no proof that climate has an important effect on its frequency. Capacity for work was reduced in most cases, and it was completely lost in 7.3 per cent of the men with an average age of 53 years and an average duration of the disease of eighteen years. Only 4.5 per cent of the women were completely invalided. In 29 per cent of the asthmatic patients there was a history of other allergic diseases such as chronic eczema, urticaria and hay fever; and in 50 per cent there was a family history of allergic disease. Apparently the asthma began at an earlier age when there was a family history of allergic disease than when there was no such history. Dr. Claussen concluded with calculations that justify the stamping of asthma as a national scourge.

BERLIN

(From Our Regular Correspondent)

Penicillin in Western Zones and in Berlin

The flow of penicillin into the Western zones and into Berlin—where all four sectors are equal beneficiaries—is now regular enough to enable military authorities to put the drug at the disposal of German hospitals for the treatment not only of venereal diseases but of pneumonia, pleurisy, pulmonary abscesses, meningitis and septicemia. The distribution is in the hands of the *Landesgesundheitsamt*. In Berlin there are twenty hospitals which have penicillin on hand; other hospitals may get it on special application. The pharmaceutical firm of Schering in Berlin is now recovering penicillin from the urine of treated patients and thus adding materially to the stocks made available from the West.

New Medical Educational Developments

(a) Foundation of the Institute for Medicine and Biology.—The Berlin suburb Dahlem, now principal residential district for the American occupation forces, is the site of the once famous Kaiser-Wilhelm-Gesellschaft, widely known center of scientific research. As early as 1946, Nobel-prize-winner Professor Warburg reopened the institution of the "Dahlem Colloquiquim" meeting place and discussion forum for leading authorities in the fields of chemistry, physics and biology. Late in 1947 the constituent meeting of the Institute for Medicine and Biology took place within the Kaiser-Wilhelm-Gesellschaft. Seven institutes and one clinic are planned for this new research institution. Two, one for biochemistry and one for theoretic physics, are already in operation. Professor Lohmann is in charge of the whole project.

(b) Courses for Physicians in the American Sector of Berlin.—Beginning in the summer of 1948, courses will be given for physicians under the sponsorship of the Department of Public Health, Berlin sector. The expenses will be covered by funds from fines imposed on Germans by the military government. The courses will be given at the two largest hospitals in the American sector. German specialists will teach in their particular fields; lectures by American physicians are also planned.

(c) Association of Psychologists.—By the recent foundation of the Professional Association of German Psychologists of Hesse, the organization of all psychologists within the British and American zones was completed. The leaders of the Hesse association are Dr. Schnehage, of the labor office in Frankfurt, and Professor Duecker, Marburg, as representative of the German Society for Psychology.

Correspondence

EVALUATION OF FOREIGN GRADUATES

To the Editor:—In the May 1 issue of THE JOURNAL there appeared on page 16 an article signed by Dr. Lochner of Albany, N.Y., concerning the evaluation of foreign medical graduates. Unfortunately, that article contains misleading statements; here is a quick review of some of the errors he committed:

First, he did not even mention the existence of a tremendous difference among the various medical schools abroad; he simply englobed all of them, failing to distinguish between the very fine colleges (e.g., Paris, Lyon, Amsterdam) and some second class schools in certain European countries.

Second, he failed to mention that among the foreign graduates who try to revalidate their medical credentials in this country, a very large percentage are American-born youths who for one reason or another went abroad to study. Thousands of American boys went to Germany, Austria, Switzerland, England and other countries in Europe. It is a sad fact, but nevertheless indubitable, that in many European medical schools foreigners, and especially Americans, had to pass much "milder" examinations than did the natives of the countries and that in many of those countries diplomas delivered to foreigners carried the famous inscription "valid only for abroad," as the respective countries did not admit them for licensure. Hence, the large percentage of deficiently trained graduates and their failures in state medical examination in this country. It is obvious, however, that the global percentage of failures of foreign graduates as indicated by Lochner in his report is entirely silent concerning this exceedingly important detail.

Third, a purely quantitative approach to the statistical analysis of failures of foreign graduates is unjust, for it fails to take into consideration the important fact that many of those foreigners are physicians who for ten, fifteen or twenty years had their practice limited to certain specialties. An otherwise brilliant dermatologist may have difficulties in passing his examination in obstetrics, or even anatomy; the same holds true - *mutatis mutandis* - for a psychiatrist, gynecologist or other specialist. Thus, to compare an elderly specialist with a young, recently graduated colleague still in practice is, to say the least, unfair.

Fourth, Lochner fails to mention the well known fact that the immense majority of foreign graduates do participate in hospital and clinic work, just as the majority of their American graduated confrères, and with the same zeal and efficiency. Moreover, many a foreign graduate became nationally famous for his important scientific contributions, and many of them occupy positions as teachers and leaders in America's foremost schools and hospitals-seemingly to everybody's satisfaction. Indeed, practically all foreign doctors in this country become citizens, raise families and become thoroughly incorporated into American life. (Incidentally, many of them marry American women.)

Fifth, concerning the moral qualities of the foreign graduates, I am convinced that no generalization could be safely sustained; just as in any other group, there are nice persons among them and also some rather reprehensible ones. However, to judge all of them bad because some of them are arrogant or unthankful to this great country would be unjust.

MARDOOUEO I. SALOMON, Sc.D., M.D., Bronx, N.Y.

To the Editor:—In an article in THE JOURNAL, May 1, Dr. Jacob L. Lochner, of Albany, N. Y., reported about "Licensure Evaluation of European Medical Graduates." As long as there are by now several thousand foreign graduates in this country who have taken their state board examinations during the last fifteen years, the problem involved is bound to arouse considerable interest and attention in many medical communities of the Unites States.

Dr. Lochner's article presented a frank and violent attack on European immigrant physicians, and, as similar articles have appeared in other medical journals, it seems appropriate to hear somebody from the other camp.

Dr. Lochner started out in dealing with the different national systems of education, and cited the reports which the Commission of Medical Education made in 1932. For the most part, also, he considered medical education in Germany. The report stated that up to 1913 medical education in Germany was as good as any in the world; that it was, *however, seriously affected by Hitler* after 1938, so that the New York Board will not recognize medical education begun in Germany after 1940. Strangely enough, no mention was made about the standard of medical training and education between 1913 and 1938, although the vast majority of those immigrant doctors who have come to the United States during the last fifteen years received their training during that period. I suppose the outcome of an investigation must not have been unfavorable; otherwise Dr. Lochner would hardly have failed to mention it.

After those spearheads, Dr. Lochner set out for a full-fledged attack against foreign graduate doctors. Without any connection with the foregoing statements, he asked, "Now, what has been their success in passing the New York medical licensing examination? Their attitude has been, and strangely enough still is, that of arrogance and superiority. The majority have shown no friendliness or thankfulness to be allowed to come to this free and democratic country...." This is about as unsemantic a statement as it is possible to make. From Dr. Lochner's own statistics, 5,025 foreign graduates have passed-not only taken-their state board examinations between 1938 and 1946. How many of these doctors has Dr. Lochner checked on, talked to or heard of as being unfriendly or not thankful toward their new country? The majority of 5,025 would be more than 2,512. Besides, does he by any chance form his opinion from the reactions of disappointment when a doctor aged 50 or more, who is financially able just to tide himself over those first few months, flunks out? Would Dr. Lochner possibly be free from any emotional reaction if he should have the bad luck to have to try again in a new country and should have to take examinations fourteen times, as did the unfortunate man whom he cited? To get a proper idea about the attitude of foreign graduates, one should judge from those who have weathered the first storm and have been in practice for a year or two—not from those who, as Dr. Lochner admits, have been here just a short time.

"Many of the foreign physicians will complain! Do they come alone to complain? No! In practically every case they bring or send a member of the legislature or even a member of Congress." I find out, again from Dr. Lochner's figures, that there were 4,036 foreign graduates who failed during 1938 to 1941. If our senators and congressmen had to take care of only a small fraction of those 4,036 cases, say one tenth, they would certainly be kept more than busy, especially as long as they still have to take care of other business.

I would not state that every physician who has undertaken to start out anew in this country has been lovable or an asset, but one should not condemm a whole group which, just on account of gratitude and, I may say, love toward this country, is badly hurt by statements as they have come out of the mouth and pen of Dr. Lochner. Just as we have been trying hard to understand and adopt the American way of thinking and acting, which I think has gradually become a part of us, it may not be asking too much for us to try to understand those who have lived mostly for more than four decades under entirely different circumstances and in an entirely different semantic environment. What seems to be arrogance and superiority is often nothing of the kind; it is a different behavior explained by different upbringing. In a German university or hospital there is always present a distinct distance between the senior physicians down through the scale of the subordinate ones. A younger doctor has been trained to respect this distance, and a certain exaggerated reverence toward the older and upper members of the staff was the natural and expected attitude. This was probably a part of the militaristic structure of every German institution. Therefore it naturally takes time before such newcomers to this country will realize that everything functions just as well, if not better, without a clicking of heels and that there is nothing wrong in greeting your superior with a simple "hello." Inhibitions have to be overcome before the lack of necessity, or even the absurdity, of keeping "distance" is fully realized. even in the intercourse with colleagues on an equal footing. This is a part of the process of assimilation and adaptation which, of course, cannot be accomplished in two or three months but which most of the immigrants are seriously striving for, and, as I know, with a great deal of ultimate success. I believe that it is this inherited and trained attitude of German immigrants which gives rise to the impression of arrogance and superiority which Dr. Lochner finds so conspicuous in them.

All mankind sighs over the deterioration of human relations. Continuance of discrimination is an intellectual and spiritual attitude which cannot and will not lead the world out of the maze in which it has lost itself. We will not be able to build up a saner and less hostile society in smaller and larger measures unless we cultivate what men have in common rather than emphasize their differences.

Medical Motion Pictures

FILM REVIEWS

Tattooing of Skin Grafts and Port Wine Stains. 16 mm., color, silent, 410 feet (one reel), showing time twelve minutes (to be run at sound speed). Prepared by Herbert Conway, M.D., Plastic Surgery Clinic, Cornell University Medical College, New York Hospital, New York. Produced in 1947 by the Medical Film Guild. New York. Procurable on loan from the author, 525 East Sixty-Eight Street New York 21.

This film shows the technic of tattooing for coloration of skin grafts on the face and the permanent camouflage of port wine stains (capillary hemangiomas) by injections of pigment. The technic of administration and the appearance of patients before and after the treatment are demonstrated. One patient with a split-thickness graft on the forehead is shown preoperatively and postoperatively. Another is shown with a spotty port-wine stain about the forehead and glabella. A few colored stills of light stains of the face before and after tattooing are used. The photography is excellent. The photomicrographs are incorrectly titled as microphotographs.

A Multiple Personality. 16 mm., color, sound, 675 feet (one reel), showing time sixteen minutes. Prepared in 1946 by John G. Lynn, M.D., and Raymond Sobel M.D., Department of Neurology, Columbia University and Psychiatric Institute, Grasslands Hospital, Valhalla, N.Y. Produced by and procurable on loan from the Medical Film Guild, 167 West Fifty-Seventh Street, New York 19.

A woman aged 24 who had been committed to the Grasslands State Hospital is portrayed as having four personalities each independent of and amnesic for the others. Under hypnosis the patient is directed to become successively Flossy, a conscience-free psychopath; Mickey, a passive, inhibited, fearful preadolescent; Florence, a naive, fearful child, and finally Miss Nelson, an affectless adult with an I.Q. of 130. The patient's posturings in these personalities are so transparent and the hypnotic technics used to effect the metamorphoses are so obviously inadequate that even an unsophisticated observer is led to wonder just who is supposed to be hypnotizing whom. The confusion is increased by many other defects in the film: slipshod photography, editing and synchronization; filled-in speeches; misplaced subtitles, and relatively pointless but persistent questionings of the patient as to whether or not she likes her physician. A final subtitle implies that the patient had been benefited by a combination of hypnotic and psychoanalytic therapy; yet in the last scene the only apparent changes in the patient's appearance and behavior are (1) a more becoming hair-do and (2) a willingness on her part to repeat various cliches to the effect that her "Flossie personality had been psychopathic," "Mickey" had suffered from a "guilt complex" and "Florence" had furnished a last escape. The film is chiefly remarkable as a throwback to the theories of Janet and Morton Prince about dissociation and splitting of the personality; as such, it might be useful in illustrating the recurrently atavistic tendencies in some psychiatric thinking.

Without critical and evaluative comment, however, it would be seriously misleading to medical students or even to physicians inexperienced in the interpretation of psychiatric phenomena.

The Surgical Treatment for Carcinoma of the Lower End of the Esophagus. 16 mm., color, silent, 1,100 feet (three reels), showing time forty-two minutes. Prepared in 1947 and procurable on loan from Philip Thorek, M.D., 25 East Washington Street, Chicago 2.

The film shows the resection of a cancer of the lower end of the esophagus through a combined abdominothoracic incision; depicting the technic of this difficult major operation. The surgical technic is excellent. The color photography is good. On two occasions the position of the camera is shifted without the audience being told of the shift. This introduces an element of confusion, and it is some time before one can again orient himself in relation to the anatomy. The film would be of particular interest to surgeons performing this type of surgery, but it would be valuable to all physicians as demonstrating the ease with which these major procedures are now being performed.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Life Insurance: Death of Insured Following Abortion.—The plaintiff, as beneficiary, sued to recover on three life insurance policies issued to the deceased by the defendant insurance company. From a judgment for the plaintiff, the defendant appealed to the court of appeal of Louisiana, Orleans.

Each policy sued on provided in effect that no benefits would be payable if the insured died as the result of a violation of the law. The death of the insured resulted from acute tetanus following a criminal abortion, to which she had voluntarily submitted.

The defendant first contended that the deceased was an accessory to the abortion, which is a crime, and that the aforementioned provisions of the policies therefore absolved it from liability. The definition of the crime of abortion as found in the Louisiana criminal code, the court said, indicates that it was the legislature's intention to make the person who feloneously administers a drug or potion or any other substance to a pregnant woman, or who uses any instrument or any other means whatsoever on a pregnant woman, for the purpose of procuring a premature delivery of the embryo or fetus, guilty of the crime of abortion. The language used in the definition is not broad enough to show an intention to include a woman who consents or submits herself to an abortion, however, even though such woman is guilty of a detestable and revolting offense against the laws of nature. The defendant is absolved from liability in this case only if an unlawful act perpetrated by the insured caused her death. If it was the intendment that the insurer would not be liable if the criminal act causing death was that of a third person, a case might arise in which an innocent policy holder, without provocation, was feloniously killed by another, in which event the insurance company would be relieved of paying the policy, as it could be said that the death arose from a criminal act, even though the insured played no part therin, except being the victim. A provision of a life insurance policy relieving the insurer from liability where death results from a violation of the law is to be given a reasonable and common sense construction. We believe, the court concluded, that the exclusion of liability clause in question was intended to apply only in cases where death resulted from a violation of the law by the insured herself.

The defendant next argued that the act causing the insured's death was of a heinous and abhorrent character and that public policy precluded insuring her against its consequences. The record does not show what relationship, if any, existed between the plaintiff and the deceased, nor is it shown that he had any knowledge of the deceased's intention to submit to the operation or played any part in it. The plaintiff, however, is the designated beneficiary and seeks the the recovery individually and for his own account. The question presented, said the court, is therefore: Should the plaintiff here, who is the named beneficiary of life insurance policies, be allowed to enforce collection of the policies where the death of the insured resulted from a criminal operation, the policies not expressly providing against the insurer's liability for death from such a cause?

It seems to be the general rule, the court of appeal said, to take into account two different classes of life insurance policies, one class being those policies made payable to the assured's estate, or to his personal representative by some appropriate designation, and the other class being those policies in which some third person is nominated and designated as beneficiary. The weight of authority appears to be to the effect that a person or his estate should not profit as a result of his own wrongdoing, and that when the maturity of an insurance contract made payable to the estate, or to the personal representative, is hastened or accelerated by his wrongdoing, even in the absence of any prohibitory clause in the contract, no recovery can be had on the policy. It is otherwise in cases involving policies in the latter class, i.e., those running in favor of third persons as beneficiaries, on the theory that the beneficiaries, having acquired a vested interest in the policies, cannot be either divested thereof or jeopardized therein, after issuance of the policies, by any wrongful act of the insured not excluded from coverage, for which they are not responsible. Even though the deceased came to her death as a result of the illegal operation for abortion to which she had voluntarily subjected herself, such submission on her part, which was reprehensible and detestable, cannot be used by the insurer as a valid defense to absolve itself from the payment of the proceeds of the policies to plaintiff, as plaintiff appears individually and as the designated beneficiary, having a vested interest in the policies. His rights as beneficiary could not be affected, and were not affected, in any way by the act of the insured, for which he was in no way responsible; there is no reason for disregarding the terms of the contract of insurance and exonerating the insurer on the grounds of public policy. Accordingly the judgment of the trial court in favor of the plaintiff was affirmed.—*Payne v. Louisiana Industrial Life Ins. Co., 33 So. (2d) 444 (La., 1948).*

Liability of Charitable Hospital for Injuries to Private Nurse.—The plaintiff sued the defendant hospital for injuries sustained by her while working as a private nurse for a patient of the defendant hospital, the injuries allegedly having been due to the negligence of an employee of the hospital. From a judgment for the plaintiff the defendant appealed to the Court of Errors and Appeals of New Jersey.

At the time of the accident the plaintiff was nursing a patient of the defendant charitable hospital, for which she was receiving $49 per week from the patient, who also paid the hospital for her meals. On Dec. 7, 1943 the plaintiff proceeded to the basement of the hospital, where the nurses' cafeteria was located; she obtained her food at the food counter and was carrying her tray from the food counter down the corridor and around a corner to the restaurant when she tripped over a pan alleged to have been placed in a negligent manner and was injured.

The question of liability of a charitable hospital to respond in damages for negligence of its servants has been many times before the courts, said the Court of Errors and Appeals. Conflict exists concerning such liability. There are two rules, the "absolute or unqualified" immunity rule and the "qualified" immunity rule, and various reasons have been given in support of each. Among those reasons are "public policy," "trust fund theory," "waiver theory" and "respondeat superior theory." The Court of Errors and Appeals then quoted from a prior New Jersey case as authority for the proposition that New Jersey follows the qualified immunity rule:

> In our state we have adopted and followed what we believe to be the majority view; i.e., the public

> policy theory. Thus we deny the right of recovery on the part of those who have a valid claim against a charitable institution, based on actionable negligence, but who are either the recipients of the benefactions, or the beneficiaries of the charitable institution sought to be held liable; but we permit the right of recovery against charitable institutions, for their actionable negligence, on the part of those unconcerned in and unrelated to that which the donor brought into being or supports in operation.

Therefore, said the Court of Errors and Appeals, the decision in this case comes within a narrow compass—was the respondent, a private nurse engaged for and paid by a private paying patient in a charitable hospital, a stranger to or a beneficiary of the charity?

The defendant contended that the plaintiff was in a legal sense a beneficiary of the charity. It conceded that if she was a stranger to the charity the judgment in her favor was well grounded. The argument, in brief, was that the plaintiff's association with the hospital was advantageous to her, in that she obtained employment through the nurses' registry maintained by the hospital and that the nurses' registry was maintained without cost to her, and gave her a preference in employment. This did not make her a participant in the hospital's bounty, however, concluded the court. She was paid by her patient, who also paid the hospital for her meals served while she was in attendance on the patient. While it was no doubt of advantage to the nurse to be on the registry, it was perhaps of more advantage to the hospital to have nursing service available, for it is common knowledge that in recent years hospitals have been confronted with a serious problem due to the shortage of nurses. But however this may be, the nurse in the service of the private patient was not a beneficiary of the charity in the legal sense. She therefore was an invitee of the hospital and a stranger to the charity, and the hospital owed her the duty of ordinary care in maintaining the premises in a reasonably safe condition. Accordingly the judgment in favor of the plaintiff was affirmed.—*Rose v. Raleigh Fitkin-Paul Morgan Memorial Hospital-Ann May Foundation, 57, A. (2d) 29 (N. J., 1948).*

Chiropractic Practice Acts: Validity of Annual Registration Prerequisite.—The plaintiffs filed a bill to enjoin the defendant board of chiropractic examiners from enforcing the provisions of the chiropractic practice act relating to annual registration. From a judgment dismissing their complaint, the plaintiffs appealed to the Supreme Court of Wisconsin.

The chiropractic practice act of Wisconsin requires all licentiates to renew their licenses annually and provides further that at the time of such annual renewal the applicant shall present satisfactory evidence to the board that he has, during the preceding year, attended at least one of the two day educational programs conducted, supervised and directed by the Wisconsin Chiropractic Association. The plaintiffs alleged that there are two statewide voluntary organizations in Wisconsin which licensed chiropractors may join. One is the Wisconsin Chiropractic Association and the other the Wisconsin Chiropractors Society. Each has a substantial membership and each provides an annual educational program. The Wisconsin Chiropractic Association requires a fee of $10 from each person who attends its annual educational program, which is the program a chiropractor must attend in order to have his annual license renewed. It is alleged that the statute does not authorize the charging of any fee and certainly not a fee in excess of the cost, which it is claimed this fee is. The plaintiffs state that they are ready and willing to pay the annual fee of $5 to the state for renewal of their licenses but claim that the portion of the statute which requires annual attendance at the educational program provided in the statute in order to have their licenses renewed is in violation of their constitutional rights and deprives them as citizens of their rights and property without due process of law.

The state has the power, said the Supreme Court, to provide for the general welfare of its people and in so doing to prescribe reasonable qualifications to be complied with before a person may engage in or carry on any trade or profession. The fact that a person is once licensed does not create a vested property right in the licensee, as advancements in the trade or profession may require additional conditions to be complied with if the general welfare of the public is to be protected.

The respondents argued that the legislature has the right to decide whether advancements in their profession require those engaged in its practice to attend educational programs in order to continue practicing. To this we agree, said the Supreme Court. If the legislature had provided that any chiropractor desiring to have his annual license renewed must attend an educational program approved by the state board of examiners in chiropractic we would have no difficulty with it, or if the legislature had adopted a standard which the program must meet it could well be argued that this would be sufficient. The statute in question goes far beyond this, said the Supreme Court. It provides who shall give the educational program that must be attended and gives them complete control of the nature of the program. Respondent would not argue that the legislature may require a person to be a graduate of one certain medical school in Wisconsin or one certain dental school in Wisconsin in order to be able to obtain a license to practice his profession in this state. This statute comparatively so provides. It provides where he must take limited postgraduate work each year if his license to practice is to be renewed. It requires the licensee each year to attend one day of the educational program provided by the Wisconsin Chiropractic Association, a voluntary organization not primarily engaged in the educational field. We do not mean to indicate that the program offered is not an excellent program and well worth attendance by every member of the profession. The difficulty is that the legislature has fixed no standard of a program which must be attended nor has it delegated to any board the authority to approve the program to be offered. It has merely provided by whom the program shall be given. In a California case, where the statute provided that the state board of medical examiners should be elected from three certain medical societies, while upholding the statute the court said it "could not be upheld at all if it were put upon the ground that in so doing the state is acting for the benefit of any one of all of the medical societies or schools of medicine existing in the state." We conclude, said the Supreme Court, that the state here was acting for the benefit of the association primarily, which is not within the legitimate exercise of police power. Accordingly the judgment of dismissal was reversed and the cause remanded with directions to enter judgment in favor of the plaintiffs.—*State ex rel. Week v. Wisconsin State Board of Examiners in Chiropractic, 30 N. W. (2d) 187 (Wis., 1947).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Control of Schistosomiasis Japonica. W.H. Wright, P.M. Bauman and N. Fry. -p. 33.
Observations on Safety of Multiple Antigen Preparations. V. K. Volk. -p.53.
Vaccination Against Q Fever. J. E. Smadel, M. J. Snyder and F. C. Robbins. -p. 71.
Survival of Virus of Common Cold in Specimens Collected from Naturally Acquired Cases of Common Cold. M. Pollard, C. U. Dernehl and C. D. Caplovitz. -p. 103.

Treatment of Head Lice.—Eddy reviews observations in over 1,000 natural infestations of head lice treated during 1944 and 1945 in Illinois and Indiana with three pediculicidal preparations, all of which had been adopted by the army during the war. Most of the persons treated were school children, but many parents and children under school age were also treated. The MYL formula is composed of 0.2 per cent pyrethrins (from a 20 per cent concentrate), 2 per cent N-isobutylundecylenamide (IN-930), 2 per cent 2,4-dinitroanisole and 0.25 per cent "phenol S" (a mixture of isopropyl and diisopropyl cresols) in pyrophyllite. The DDT powder contains 10 per cent of DDT in pyrophyllite. The NBIN emulsion is prepared from a concentrate containing 68 per cent of benzyl benzoate, 14 per cent of Tween 80 (polyoxyalkylene ether of sorbitan mono-oleate), 12 per cent of ethyl aminobenzoate and 6 per cent of DDT. One part of the concentrate is diluted with 5 parts of water before using. All the persons treated were infested with either lice or eggs. Before treatment only 20 of the 222 persons treated with the MYL powder were found to harbor lice; 63 of the 178 treated with the DDT powder had active forms present; and 171 of the 636 treated with the NBIN emulsion were found to be infested with lice. Probably motile forms were present in many instances but were not detected. On examination eight to ten days later no live lice were found following the use of DDT or NBIN, but on 3 persons treated with MYL live lice were present. The MYL powder cannot be depended on in all instances to give complete control in one application.

Efficacy of Chemotherapy in Quartan Malaria.—Young and Eyles point out that because of its low prevalence in most parts of the world and because of its being less dramatic than the other forms of malaria, infection due to Plasmodium malariae, or quartan malaria, has received less attention in experimental chemotherapy. The general impression seems to be that the parasites of P. malariae in the peripheral blood stream tend to resist the action of drugs longer than the other malarial parasites. The object of the present report is to compare the effects of quinacrine hydrochloride ("atabrine"), quinine sulfate, totaquine and a newer drug, chloroquine (SN 7618: 7-chloro-4-[4-diethylamino-1-methylbutylamino] quinoline), on this species of malarial parasite. Infections were induced by injections of malaria-infected blood into 79 neurosyphilitic patients. The authors then tested the efficacy of chloroquine, quinacrine, quinine and totaquine. Chloroquine gave the best results. Quinacrine was better than quinine. Totaquine gave the poorest results. P. malariae responded relatively slowly to all the drugs tested. Using chloroquine regimens, patients were fully cleared of P. vivax in the peripheral blood much faster than of P. malariae, even though the densities of the P. vivax parasites were several times greater at the beginning of treatment.

Transmission of Wuchereria Bancrofti.—Giglioli says that in a recent study of the house-frequenting habits of the mosquitoes of the coastland of British Guiana it was found that only three of the many species inhabiting this region can be regarded as habitual house frequenters and man biters. These are Culex fatigans, Anopheles darlingi and Aedes aegypti. The work here reported was undertaken to establish the relative roles of these three species in the transmission of Wuchereria bancrofti. A. darlingi is just as suitable a host for Wuchereria as C. fatigans, its classic vector; the specific anthropophilic feeding habits which cause A. darlingi to be the most effective malaria carrier of Equatorial America obviously also make this mosquito a particularly dangerous vector of filariasis. Attempts to infect Aedes aegypti experimentally failed entirely, and the negative role of this species in the transmission of Wuchereria was confirmed.

Antireticular Cytotoxic Serum in Hodgkin's Disease.—The study which Skapier undertook was to determine the therapeutic value, if any, of antireticular cytotoxic serum (A.C.S.) in a disease specifically involving the reticuloendothelial system, such as Hodgkin's lymphogranuloma, which is regarded as a malignant type of reticuloendotheliosis of unknown causation. Antireticular cytotoxic serum was used in the treatment of 22 selected patients with Hodgkin's disease, but it did not prove to be a curative agent in this disease. However, the majority of the patients treated showed improvement in the general condition, such as gain in body weight, favorable changes in the sedimentation rate and blood morphology. The author thinks that antireticular cytotoxic serum may be considered a valuable adjunct to other accepted methods of therapy in the treatment of Hodgkin's disease.

Apparent Anticarcinogenic Action of Lanolin.—Berenblum and Schoental point out that because some investigators observed that addition of wool fat (anhydrous lanolin) to oils or tars often led to a reduction in their neoplastic response, the use of this agent was recommended as a preventive against occupational cancer. The authors made further investigations on this problem and were able to confirm the striking diminution in the carcinogenic potency of methylcholanthrene, which occurs when wool fat is used as the diluent. This was found to operate also in connection with another carcinogen 9,10-dimethyl-1,2-benzanthracene. In both cases, however, the inhibitory effect was completely nullified when the concentration of the carcinogen was raised. Furthermore, in the lower concentrations, analogous diminution in carcinogenic potency was obtained by substituting liquid paraffin for wool fat as diluent. These results are incompatible with the idea that the inhibitory effect of the latter constitutes a specific anticarcinogenic action. They are readily accounted for on grounds of inadequate concentration. In view of this, the use of wool fat as a preventive measure against occupational cancer would seem to be of doubtful value.

Fracture of the Femoral Neck.—Dissection and roentgenographic analysis of the upper portion of the shaft and neck of the femur revealed to Farkas and his associates a highly independent laminar bony system, which begins from 2 to 4 cm. below the lesser trochanter and ends in fanlike fashion at the cartilaginous plate of the head. This proved to be the internal weight-bearing system of the proximal portion of the femur. This system undergoes slow resorption in its distal portion after middle age, but it never disappears. On the roentgenogram it can be seen throughout life from its distal to its proximal end. Microscopically, it consists of a great number of laminas and bone cells, and a rich endosteal lining; hence the speed with which it is capable of new bone formation. Mechanically, the internal weight-bearing system is a compression system, and during weight bearing it is to be found almost in the vertical plane. Preceding adduction fractures, the internal weight-bearing system is resorbed and replaced by cortical bone in its entire distal portion. Its proximal end remains spongy, with laminar character. The separation occurs at the site where the spongy proximal portion begins and the distal cortical portion ends.

In abduction fractures the internal weight-bearing system suffers only trauma, but otherwise it is strong. This explains the rapid healing of such fractures. On the basis of the anatomy and pathology of the femoral neck, two types of fracture may be distinguished: (1) compression fractures, comprising the abduction, intermedial and adduction fractures, and (2) subcapital separations, represented by most fractures of the aged. The prognosis of the compression fractures is good, if the fragments are kept in good apposition and fixation in plaster, in Russell traction or by nailing. For the treatment of the adduction fractures, a method with a perforated (sieve) sublay graft has been developed.

Fractures and Dislocations Caused by Parachute Jumping.--This survey by Ciccone and Richman describes 3,000 fractures and major injuries to soft tissue as the result of parachute jumping, with particular reference to the traumatic mechanisms involved. Almost all injuries involve weight-bearing structures and can be attributed to four basic traumatic mechanisms: (1) torsion plus landing thrust; this is by far the most common mechanism of injury and is responsible for a chain of related injuries, extending from the toes to the hip. (2) Backward landing; vertebral compression fractures and head injuries characterize this mechanism of injury. (3) "Opening shock" is a mechanism of injury peculiar to parachute jumping. The violent abduction stress causes many ligamentous tears and even fractures of the extremeties. (4) Violent vertical landings, occasional parachute malfunctions increase the landing impact and cause severe multiple fractures of the legs and spine. One half of all parachute fractures involve the ankle mortise. The most prevalent mechanism of injury is external rotation, which, together with abduction, accounts for approximately 75 per cent of fractures at the ankle. The entire lower extremity shows a preponderence of external-rotation injuries. This would imply a structural weakness of the limb as a whole,—a lack of adaptive resiliency to the stress of external torsion. A classification of fractures based on etiologic stresses is more useful than one based on anatomic location. Recognition of the etiologic stresses provides a rational approach to treatment.

Tuberculosis of Trachea and Bronchi.—Sweany and Behm say that with the increase in the use of the bronchoscope many hitherto unsuspected cases of tracheobronchial tuberculosis have been discovered in patients previously thought to have only pulmonary tuberculosis. Notwithstanding the importance of bronchoscopy, it has been necessary to resort to postmortem examination to determine the large incidence of these complications. This report involves the analysis of 667 necropsy specimens of pulmonary tuberculosis in which the trachea and the main bronchi were systematically studied. Gross evidence of tuberculosis was found in 377 cases (56.5 per cent). Microscopic study of a sample of grossly negative specimens gave an estimated figure of 37.5 per cent of lesions in the remaining 290 cases, thereby increasing the positive findings of all cases to 72 per cent. The incidence was increased in the young age groups and in the female sex The pathogenesis seemed to be best explained by a direct implantation of bacilli in the mucous glands, or through breaches in the epithelium. The location of lesions in the tracheobronchial tree was more or less random, although points of stress (larynx), posterior aspects of the tracheobronchial tree and areas in proximity to cavities seemed to be affected most. The nature of the involvement was diffuse superficial infiltration in 12 cases; diffuse and deep infiltration and ulceration in 85 cases; circumscribed ulceration in 265 cases; fibroid stenosis in 5 cases; perforation in 6 cases, and caseous bronchitis in 4 cases. The hope for the future of tuberculous tracheobronchitis seems to be for early bronchoscopic study of all cases, early diagnosis and early treatment in positive cases by thoracoplasty or streptomycin, or both.

Synergism Between Mycotic and Tuberculous Infections of Lungs.—Greer aims to refute the impression that coexisting fungi are harmless saprophytic invaders and to advance added data to support the premise that an infection of the lungs with pathogenic fungi in association with a tuberculous infection of the lungs is not harmless and coincidental, but that it definitely increases the activity and virulence of the tuberculous process. He discusses the commensal relationship between fungus and tuberculous infections of the lungs. The coexistence of these two infections produces a more rapidly fatal issue in tuberculous persons than one should expect from the duration of the disease process in the lungs. Fungi from the expectorated sputum are usually saprophytic. It is best to obtain the sputum specimens by intratracheal aspiration and to subject the fungus to animal inoculation if there is any doubt regarding its pathogenicity. Physicians should search diligently for coexisting pathogenic fungi in every tuberculous patient whose clinical course is unusually rapid or prone to relapse. In 5 among several hundred patients in whom tuberculosis had been diagnosed clinically the author found pathogenic fungi in the tracheal secretions, although tubercle bacilli were never recovered from these 5 patients. The mycelial fungi are found more frequently than yeastlike fungi as the etiologic agents of pulmonary mycoses associated with pulmonary tuberculosis. All ideas dealing with the cooperative relationship between the tubercle bacilli and fungi existing together in diseased tissuee are highly speculative, as little, if anything, is known regarding such interacting or interplaying processes. The investigations reported here would suggest that the association of a fungous infection of the lungs in a patient having pulmonary tuberculosis would augment and accelerate the activity of the tubercle bacilli either directly or by lowering the vitality and resistance of the patient.

Silicosis in British Columbia.—Vrooman says that in 1935 a survey was made of five of the leading metalliferous mines to obtain a cross section of the prevalence of silicosis. Of those examined, the total number of miners who had worked five years or more underground was 703. Of that number 105 had silicosis. Nearly two thirds of these had the first stage of silicosis, and the others showed signs of disability. Following this survey, silicosis was made a compensable disease. It was made compulsory for mine owners to have their underground employees given a yearly examination with roentgenogram of the chest. These examinations are made by the mine physicians. The examination forms and roentgenograms are forwarded to the Workmen's Compensation Board and reviewed there by the silicosis referee, who may cancel or reissue any certificate if he considers it advisable. The policy is that all patients with suspected active tuberculosis shall be excluded. Those whose silicosis shows progression or is complicated by tuberculosis are advised to apply for compensation, and they are removed from underground work. Those with early silicosis which is not showing progression, especially the older men, are issued certificates if they wish to continue to work underground. The disease of these patients does not progress much faster if they were allowed to remain at the work to which they are accustomed than if they are removed. It is an economic disaster to remove men from work they have been doing for fifteen or twenty years and ask them to make a living at something else. Most of the mines of British Columbia are now reasonably safe. In September 1937 the Workmen's Compensation Board appointed a competent dust inspector to visit the mines at regular intervals and to make dust counts and recommendations regarding improvement of ventilation.

Surgical Management of Intracranial Suppuration.—Since penicillin and sulfonamide drugs have been used for treatment, Gurdjian and Webster have treated by operation 16 patients with intracranial suppuration. These included 1 left frontal extradural abscess, 3 subdural abscesses, 11 cerebral abscesses and 2 cerebellar abscesses. One instance of cerebral abscess was associated with subdural suppuration. Most of these patients had a history of infection of 1 month's duration or longer. The analysis of the records of these patients has emphasized the desirability of a step by step plan of surgical management for intracranial suppuration. Such a plan employs the simplest surgical procedure first. This consists of tapping the abscess and the instillation of penicillin. Time is allowed for resistance of the host to develop. Repeated tapping is usually required. If tapping and instillation of penicillin are not successful, excision of the abscess can be undertaken. Ventriculography may be used to localize the extent of the purulent mass. Excision of the abscess can then be done through an appropriate osteoplastic craniotomy. In the presence of a subdural abscess the plan of multiple trephine openings, exploring the cerebral surface bilaterally, is successful. Penicillin may be instilled through a rubber catheter. After the injection the tube is removed. If a cure appears to be effected, a pneumoencephalogram before discharge from the hospital should rule out any remaining focus and particularly a latent associated cerebral abscess. The wounds may be reopened for inspection of the subdural space and instillation of penicillin.

Residual Sympathetic Pathways After Paravertebral Sympathectomy.—Ray and Console designed a simple dermometer for their studies on skin resistance. They conclude that after excision of the paravertebral ganglionated chain, regardless of the extent of the excision, residual sympathetic pathways to the lower extremity remain. These pathways do not pass through the paravertebral sympathetic chain. Sympathetic activity is present in all patients in the twelfth thoracic to the third lumbar dermatomes after standard sympathectomies and may be interrupted by anterior rhizotomy, spinal anesthesia, tetraethylammonium and procaine block or division of the lumbar nerves. There may be similar pathways distributed to the face, the lower sacral dermatomes, the axilla and first and second thoracic dermatomes, and scattered areas on the trunk. After paravertebral sympathectomy these pathways become manifest only after a process of readjustment takes place. An incomplete denervation may therefore mimic complete denervation for a period up to three months. Returning sympathetic activity within this period is due to readjustment. Later return may be due to the same mechanism, to invasion by fibers from adjacent areas not denervated or to regeneration. It is doubtful if any of the present methods of sympathectomy result in a complete interruption of sympathetic pathways. Long-lasting sympathetic denervation of a part of the body may require complete denervation of not only the desired area but the adjacent areas.

Treatment of Diabetic Coma.—Marble shows that it is the careless patient, the patient with poorly controlled diabetes, in whom diabetic coma is most likely to develop. This indicates the importance of education of the patient and his family with regard to the disease. Patients make errors which may precipitate diabetic coma. Even well trained patients omit insulin during times of acute illness when food intake is scant. The patient, fearing hypoglycemia, reasons: "If I don't eat, I should not take insulin." The result is increasing hyperglycemia with the development of acidosis and eventual coma. Patients must be made to understand that in acute illness insulin must be continued, and if the illness is accompanied by fever an even greater dose of the drug may be necessary. The most treacherous pitfall in the treatment of diabetic coma is the danger of giving too little insulin, because of an unwarranted fear of hypoglycemia. As soon as the diagnosis is made, a preliminary large dose of unmodified insulin, at least 50 units and in most patients 100 units, should be given subcutaneously. A second common pitfall is the danger of not replacing adequately the fluid and electrolytes lost by diuresis and vomiting. Administration of dextrose during the first few hours of treatment is regarded by the author as another pitfall. He lists reasons why the use of dextrose parenterally during the first few hours has no place in treatment. When consciousness has been regained and an hour or two after vomiting has subsided, fluids by mouth should be begun. After preliminary trials with water, warm broths, thin gruel, tea with sugar, orange juice and ginger ale should be given at a rate of 100 to 150 cc. an hour. After the initial large dose of insulin has had the desired effect, further administration of insulin may be made, at first hourly and later at two, three or four hour intervals, according to the results of the Benedict test for sugar in urine. Within eighteen to twenty-four hours, a soft solid diet may be begun and use of protamine zinc insulin started.

Treatment of Poliomyelitis.—This discussion by Gurewitsch and his associates is based on the study of 552 paralytic patients in the acute and early convalescent stages who were treated from 1942 through 1946 at the New York State Reconstruction Home. Spontaneous pain can be eliminated by proper positioning of the patient and by measures of support. Pain on squeezing and on motion of a joint is best treated with moist heat. The authors have been prescribing hot packs extensively. Passive exercises to all joints are started from admission of the patient. With gradually subsiding pain the vigor of the passive motion is increased. Muscular reeducation should be graded carefully, and care should be taken to avoid exhaustion of a weak muscle. Ambulation is allowed as soon as it is considered that the upright posture and the effort of walking will not affect recovering muscles unfavorably. At first patients are placed on their feet in warm water up to the neck. This eliminates gravity and stimulates a multitude of postural reflexes without fatiguing muscles by weight bearing. By gradually reducing the level of the water, the amount of weight bearing is graded. Functional occupational therapy, given for the double purpose of recreation and training of muscles and skills, is used extensively in this phase. If deformities occur or increase in spite of the early application of heat and stretching, they must be corrected by methods of traction, wedging or turnbuckle casts. If deformities develop and will not yield to conservative means of therapy, surgical correction will be necessary.

Hiatus Hernia Confused with Coronary Thrombosis.—Linn reports 3 cases of hiatus hernia which were originally diagnosed as coronary thrombosis. These cases demonstrate that hiatus hernia may mimic angina pectoris and coronary thrombosis. The serious prognostic outlook in coronary thrombosis or angina pectoris makes it important that the true cause for thoracic pain be ascertained. The pain of hiatus hernia is probably initiated over the visceral afferent fibers that supply the esophagus and cardiac portion of the stomach or over the sensory afferent fibers from the diaphragm, contained in the phrenic, middle or lower thoracic nerves; thus, the pain is referred to the same segments as is cardiac pain. Overdistention or irritation of the herniated portion of the stomach may be responsible for the production of the anginal or coronary type of pain. It is important to remember that the angina-like pain of hiatus hernia is more apt to be associated with eating than with effort. The patient usually complains of a good deal of eructation and feels better when he is up and around.

Streptomycin in Granuloma Inguinale.—Olansky, Farrington and Riley say that although antimony compounds have been effective in the treatment of granuloma inguinale, adequate treatment with these drugs is difficult because of the long periods of time required and the toxic reactions which sometimes develop. The authors report the case of a Negro whose inguinal lymph nodes enlarged and broke down some months after he had had a "sore" on the glans penis. The serologic test for syphilis and the Frei and Ducrey tests for venereal lymphogranuloma were negative, but scrapings from the inguinal lesions showed Donovan bodies. The patient received an antimony preparation intravenously at irregular intervals, but the lesions became more extensive until he became incapacitated and was hospitalized. Streptomycin therapy in doses of 0.6 Gm. intramuscularly every four hours was started immediately. A total dosage of 32.4 Gm. was given. Continuous compresses of potassium permanganate in a dilution of 1:4,000 were applied to the lesions. On the third day of streptomycin therapy repeated smears for Donovan bodies showed diminution in their number. After the fifth day, no Donovan bodies could be demonstrated. When he was discharged the lesions were less tender and acute; beginning epithelization was visible. About a month later, he returned to the outpatient clinic remarkably improved. There was 75 per cent epithelization of the lesions, and the patient was comfortable enough to resume work. It is hoped that the treatment of additional cases by this method will prove that the initial good results are permanent.

*Treatment of Herpes Zoster with Cobra Venom and Sulfanilamide. M. G. Tan and Antonia R. Ines-Tan. -p. 593.

Cobra Venom and Sulfanilamide in Herpes Zoster.—Tan and Ines-Tan used cobra venom and sulfanilamide in the treatment of 5 patients with herpes zoster. The initial dose of 1 cc. of the 1:10,000 dilution of cobra venom gave no relief, but the second dose of 1 cc. in the 1:5,000 dilution decreased the intense burning and itching pain in 2 of the patients. Complete relief from pain was obtained by a third dose (1:5,000) in 4 of the patients, whereas the other patient required two additional doses. The venom injections were given alternately into the deltoid region and into the buttocks. Simultaneously with the administration of cobra venom, the patients were given sulfanilamide in doses of 10 grains (0.65 Gm.) for adults and 5 grains (0.32 Gm.) for a girl aged 7 years, every four hours night and day until the eruption disappeared completely. All 5 patients were benefited, and there were no unfavorable reactions.

Testosterone in Breast Cancer.—To aid in determining the value of testosterone therapy of cancer of the breast, Jones made observations on 15 patients under treatment with this agent. Patients were given 300 mg. of the drug per week in divided doses. Three of 5 patients with metastases to the bone had clinical and roentgenographic evidence of healing; another had relief of pain but steady progression of the lesion; in 1 instance treatment was a complete failure. Two of 10 patients with extraskeletal metastases showed startling improvement, but the remainder were failures. The variability of response noted in this and other series of carcinoma of the breast treated with testosterone is not at all understood and warrants further study.

Endemic Typhus in Baltimore.--Davis and his associates say that the City Health Department of Baltimore has recorded 59 cases of typhus with 13 deaths during the last twenty years. In October 1946, after a lapse of nearly three years since report of a case of typhus, a disease unmistakably identified as endemic typhus developed in a child living in a crowded row-house. From this row, during the next four months, 5 more cases, 1 of them fatal, were reported. A physician participating in the necropsy of the fatal case contracted the disease. Diagnosis of endemic typhus was supported in each case by results of laboratory tests. The patients lived in a row of sixteen old houses located across from a railroad and truck terminal, where freight from areas of the country where endemic typhus is comparatively common is handled and unloaded. These houses had been remodeled under the Federal Homes Use program to provide housing for war workers. All families had access to the basements, where they did their laundry and deposited their garbage in uncovered containers. In remodeling the houses nothing had been done to make the basements ratproof. Numerous openings in the walls permitted rats to enter. Complement fixation tests on blood from persons living in the infected area indicated that missed cases of endemic typhus are not uncommon. To prevent spread of the outbreak, rats and fleas were eradicated and many exposed persons received endemic typhus vaccine. No new cases developed subsequently.

*Streptomycin in Human Plague. P. V. Karamchandi and K. Sundar Rao. -p. 22.

Tetraethyl Ammonium Bromide in Hypertension.—This investigation by Hayward was undertaken to determine whether the administration of tetraethyl ammonium bromide would be a useful preoperative test in the selection of hypertensive patients for sympathectomy. He found that its administration to patients with essential hypertension leads to a considerable fall in blood pressure in nearly all cases. This is caused by paralysis of the autonomic ganglions, with a resultant blocking of the efferent sympathetic vasoconstrictor impulses. After intravenous injection the blood pressure remains low for five to thirty minutes; and after intramuscular injection, for two to eight hours. Tetraethyl ammonium bromide is less effective than sympathectomy in producing a maximal degree of vasodilatation. Patients with hypertensive heart failure have temporary relief of orthopnea and dyspnea when the blood pressure is lowered with tetraethyl ammonium bromide. There is an increase in the vital capacity, tidal air and pulmonary ventilation per minute, with a fall in venous pressure. Pulmonary congestion is probably diminished as a result of the extensive peripheral vasodilatation. Tetraethyl ammonium bromide may be useful in the emergency treatment of acute left ventricular failure. In patients with chronic congestive failure the fall in urinary output which results from the lowering of blood pressure makes the use of tetraethyl ammonium bromide inadvisable at present.

Action of Tetraethyl Ammonium Bromide.—Boyd and his associates studied subjective phenomena and changes in pupils, blood pressure and pulse rate in 50 persons, 25 of whom served as controls. Of the other 25 patients, 15 had obliterative vascular disease with or without hypertension and 10 were subject to vasospastic episodes. The authors found that tetraethyl ammonium bromide has a limited practical value in the study of the peripheral vascular response to sympathetic block and in no way compares with such reliable and proved tests as local nerve block or paravertebral block.

Streptomycin in Human Plague.—Karamchandi and Sundar Rao report that 5 patients who were practically moribund with plague were treated with intramuscular injections of streptomycin, 0.125 Gm. being administered every three hours. The outbreak of plague occurred in the Anantapur district of Madras Presidency, and so far 152 cases have been observed, with 66 deaths. The 5 patients treated with streptomycin are all alive and well today. The streptomycin treatment was usually continued for three to four days. Most of the patients received a total of 4 Gm. of streptomycin. Improvement was usually noticeable after 1.5 Gm. had been given, or after about thirty-six hours. No adjuvants were given with the streptomycin and all cases had been bacteriologically verified as plague.

Spinal Fusion in Arthrogenic Sciatica.—West reviews the position which the operation of spinal fusion holds in the treatment of that type of sciatica which is thought to be due to changes in the posterior intervertebral or apophysial articulations of the lower lumbar segment of the spine; he discusses 52 patients so treated. He is not dealing with herniation of the disk causing compression of a nerve root, the accepted treatment for which is removal of the disk substance. It is not his practice to follow this by fusion unless the disk is so much damaged as to lead to instability and arthritic changes in the posterior joints. In the cases under review, in the arthrogenic type the sciatica is presumably produced by irritation of the funicular segment of one or more nerve roots where these lie in close proximity to the arthritic apophysial joints, with associated vascular changes. Swelling and redness of a nerve root have been seen at operation in cases in which no protrusion of the disk could be found, but fusion has cured the condition. Thirty-seven of the 52 patients who have been subjected to fusion operation have been followed. In 26 of these the operation gave complete and lasting relief; in 7 others the results were fair and in 4 the treatment was a failure. One of these 4 patients died of paralytic ileus four days after operation. In 2 of the other 3, in whom the fusion was done with iliac bone, the bone has been absorbed and fusion has not occurred. The remaining patient appears to have good fusion. He has lost his sciatica but complains of pain, which appears to originate in the area from which the iliac bone was taken.

*Dermatoses and Porphyria. J. Gomez Orbaneja and H. Castro Mendoza.—p. 327.
*Desensitization in Urticaria Produced by Bread. H. Stauffer.—p. 352.

Dermatoses and Porphyria.—Gomez Orbaneja and Castro Mendoza investigated the possibility of a connection between the excretion of porphyria and dermatoses in which photosensitivity plays a part. No connection could be observed between the quantity of porphyria excreted and sensitivity to light. In some cases treatment with aminonicotinic acid resulted in improvement and was followed by an increased elimination of porphyrin.

Desensitization in Urticaria Produced by Bread.—Stauffer reports the case of a woman, aged 46, in whom urticaria developed, first on the arms, then over the entire body. Cutaneous tests with various foods proved negative, except those with bread. The patient was told to abstain from bread and was subjected to autohemotherapy. The urticaria disappeared and did not recur as long as the patient abstained from bread and from other foods made of dough. Desensitization with an antigenic extract made of bread was carried out and proved successful in that the patient was again able to eat bread and other foods prepared from flour without the development of urticaria. The preparation of the extract is simple. The author stresses that this form of desensitization is of great importance in medical practice.

*Deficient Diet and Diabetes Mellitus. O. Feuchtinger.—p. 689.
Immunity After *Immunization Against Diphtheria*. O. Guthof.—p. 707.
*Pulmonary Fibrosis Caused by Sillimanite. H. Gärtner and C. van Marwyck.—p. 708.
*Unusual Case of Acute Intoxication by Benzene. H. Robmann.—p. 712.

Deficient Diet and Diabetes Mellitus.—Feuchtinger describes observations on diabetic patients made during the latter part of the war and during the postwar period when the insulin supplies were reduced and the diet became steadily more restricted. At the time of the invasion and capitulation and during the first months of occupation by the allies, the daily dietary intake was frequently only 1,000 calories or less. During this time when diabetic persons were not provided with special additions to the famine rations, that is, from April 1945 to December 1945, the author studied 50 diabetic patients who had previously been under his observation. About half of them received insulin. He found that with one or two exceptions all patients with diabetes mellitus showed improvement in their metabolic status. There was a parallelism between the reduction in calories and the improvement in metabolism. The blood sugar decreased as did also the glycosuria and the insulin requirements. The improvement in the carbohydrate tolerance persisted in about half the patients after the dietary calories were somewhat increased.

Pulmonary Fibrosis Caused by Sillimanite.—Gärtner and van Marwyck point out that in the case of pneumonoconiosis under consideration it was first assumed that corundum might be the cause, but since corundum has been proved harmless, further studies were made on the factory dust as well as on a piece of lung tissue. The examination revealed similarity between the residue obtained from the pulmonary tissue and the dust found in a smelting furnace. This dust consisted of corundum, bauxite, amorphic silicic acid and a silicate that resembles sillimanite. Histologic studies revealed changes that have been produced in animals by sillimanite. The authors deduced that the harmful substance in the case under consideration was a substance resembling sillimanite, perhaps in connection with the amorphic silicic acid. Pneumococcus infection may have further complicated the fibrosis resulting from sillimanite.

Benzene Poisoning.—Robmann reports the case of a man who was found unconscious in a path between benzene tanks, where considerable quantities of purified benzene had leaked out. The patient was unconscious, the reflexes were abolished and the pupils were dilated and did not react. The breath had a benzene odor, and some parts of the clothing were saturated with benzene. After the patient had been undressed, nikethamide and oxygen were given. During an attack of tonoclonic convulsions, blood pressure was up to 200, whereas it had been 120 systolic and 70 diastolic at the time of admission. The pulse was regular but the count was increased. When the patient regained consciousness after forty-five minutes, he complained of headaches and dizziness. At the end of ninety minutes he experienced itching at the sites which had been in contact with the benzene. Blisters surrounded by red areas appeared. On the following day, pulse irregularities with a frequency of 100 per minute were observed and electrocardiography revealed arrhythmia on the basis of an auricular flutter and irregular extrasystoles of the left ventricle. The patient complained of pressure in the chest. Treatment with quinidine was instituted. The cardiac irregularities disappeared after several days, and the cutaneous lesions healed. The author points out that absolute arrhythmia resulting from auricular flutter is not characteristic for benzene poisoning.

*Pharmacodynamic Properties of Tanglefoot (Karwinskia Humboldtiana). M. D. Rivero. -p. 1.

Pharmacodynamic Properties of Tanglefoot.—Tanglefoot (Karwinskia humboltiana) is frequently found in some states of the United States and Mexico. It is toxic for man and animals, mainly cattle, goats, sheep and chickens. Tanglefoot causes diarrhea, which appears early in the course of poisoning and then subsides. The greater toxicity of the plant is for the central nervous system, the fruit causing paralysis of the legs and later on paralysis of the whole body and death by asphyxia. The fruit causes nervous symptoms, hyperesthesia to temperature and to pain, somnolence and blindness in the course of paralysis. As a rule the poisoning follows a fatal course. Recovery occurs only in cases of poisoning from consumption of an extremely small piece of the fruit. Cases of collective poisoning have been reported in the literature, with an erroneous diagnosis of cases of rare epidemic diseases. The author carried on experiments on pigeons. From her results she concludes that: The poison substance is mainly concentrated in the teguments of the almond seed. It is soluble in chloroform sulfuric ether, methyl alcohol and benzene. The toxic substance causes selective damage on the brain stem of domestic pigeons. The time between poisoning and the appearance of toxic symptoms and the acuteness of the symptoms depend on the amounts ingested. The greater the doses of toxic substance the more rapid the absorption of the substance by the body and the appearance of symptoms and also the more acute the symptoms and course of the disease.

Book Notices

Dermatology in General Practice. By Sigmund S. Greenbaum, B.S., M.D., F.A.C.P., Professor of Clinical Dermatology and Syphilology, University of Pennsylvania Graduate School of Medicine, Philadelphia. Fabrikoid. Price, $12. Pp. 889, with 846 illustrations. F. A. Davis Co., 1914-16 Cherry St., Philadelphia 3, 1947.

A book of dermatology emphasizing the problems met in general practice is needed. It is still needed. As the choice of the experts of some of the special sections was fortuitous, the articles on peripheral vascular diseases, the exanthems and the diseases of the oral mucous membranes are excellent. The articles on pruritus and syphilis are also commendable. Attention is called to a short chapter on page 166 emphasizing that there is no reason to believe that inadequate surgery can be salvaged by anything short of a carcinocidal dose of irradiation. This is a valid statement regarding the problem of postoperative irradiation of cancer in any location

There are some controversial statements, which cannot go unchallenged: that the addition of cystine to the diet favors the growth of hair; that poor scalp hygiene plays a role in premature alopecia; that massaging and ultraviolet ray are effective in the treatment of premature alopecia, and male hormones in senile baldness (remember that eunuchs are not bald); that tar soap is preferable as a shampoo for dry scalp; that dull hair is the result of insufficient brushing and combing; that scalp massage improves circulation in the hair follicles; that henna is a safe vegetable hair dye; that psoriasis is a disease of the healthy person; that the etiologic basis of rosacea (a vasomotor instability) is closely allied to that of acne vulgaris (a disease of the pilosebaceous apparatus); that some dermatoses are the patient's solution of an emotional conflict and that some are best left untreated; that acetylsalicylate seldom produces cutaneous lesions, and that pityriasis rosea is not contagious.

It would seem also that the general practitioner needs to be informed more about drug eruptions caused by sulfonamide drugs, gold, penicillin and barbiturates. Among important omissions are the following: quinacrine is the probable cause of "jungle rot"; patients with erythema nodosum should be put to bed; use large hot fomentations for boils; proper footgear for dermatomycosis pedis and pressure for periarticular cysts. The inclusion of multiple idiopathic pigmented hemorrhagic sarcoma with sarcoma cutis and acute disseminated lupus erythematosus with tuberculosis cutis is misleading. Greater care in proof reading would have obviated such mistakes as occurred; page 220, corporis instead of corpus; page 666 under prophylaxis should read: "This consists of adequate disinfection of the clothing and bed linen"; on page 686 use of the word "dermic" is questioned.

Contact Lenses. By Theo. E. Obrig, A.B., President, Obrig Laboratories, Inc., New York. Second edition. Fabrikoid. Price, $8. Pp. 546, with 204 illustrations. Obrig Laboratories, Inc., 49 E. 51st St., New York 22. 1947.

This is the second edition of the book intended for the optician and optometrist rather than for the opthalmologist. The chapter on anatomic data is elementary, as is that on biochemistry and physiology. Chapter III discusses conditions for which contact glasses are prescribed. The author includes retinitis pigmentosa in which he says that contact lenses are a means of prolonging useful vision. He cites 2 cases, both of highly myopic persons. The only proper conclusion he can draw is that his 2 (14 and 20 Δ) myopic patients, who had retinitis pigmentosa, saw better with contact glasses. He discusses optics and fitting and devotes a chapter to solutions used with contact lenses. The final one hundred and sixteen pages are devoted to patents for contact glasses.

L'hyperinsulinie: Les états de suractivité fonctionnelle du pancreas endocrine en médecine expérimentale et en clinique. Par Marcel Sendrail, professeur de pathologie générale a l'Université de Toulouse, Toulouse. Paper. Price, 500 francs. Pp. 256, with 30 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^{e}, 1947.

This excellent monograph will aid any student of hyperinsulinism. The author has been interested in hyperinsulinism for fifteen years. The volume of two hundred and fifty six pages contains twenty-five figures, 5 colored plates and seven chapters with a bibliography so extensive that it exceeds expectation. The literature is carefully reviewed, and the author's own investigations are presented without dogmatism.

In chapter 1 an excellent review is given of the experimental etiology of diabetes. The hypersecretion of the two minor hormones, vagotonin and lipocaic, as well as of the major hormone, insulin, may be accompanied by the hyposecretion of one of the other hormones. Rightly the author discerns the lack of close correlation between hyperplasia of islet cell tissue and overproduction of insulin, making the diagnosis of hyperinsulinism difficult from the histologic appearance of the pancreas. Incidentally, the five types of cells found in the pancreas, varying principally according to granules, are mentioned: (*a*) those with alpha granules, possibly producing lipocaic; (*b*) the most numerous of all, with beta granules producing insulin; (*c*) with no granules, found only in the guinea pig; (*d*) few in number and of unknown function, and (*e*) found only in the opossum. The innervation of the islets by the stimulating fibers of the right vagus in contrast to the opposite effect exerted by the fibers of the sympathetic system is emphasized. His own experimental work showed that prolonged fasting in the experimental animal produces hyperplasia of type a cells, thyroxin of b cells and gestation of both types.

In chapter 2, on experimental hyperinsulinism, he discusses the exogenous administration of insulin and endogenous stimulation of the animal's own secretion. The absence of quantitative relationship between the level of glycemia and symptoms is plainly brought out, and also the fact that convulsions following injections of protamine zinc insulin may occur even when the blood sugar has begun to rise following a severe depression, and that these may not respond to the administration of dextrose. He has observed the permanent cortical changes from prolonged hypoglycemia but apparently has not encountered many of those pathetic cases in which death occurs after weeks or months of a vegetative existence. He recognized that the changes in the brain are similar to those in eclampsia, uremia, lead poisoning and other conditions which produce cerebral anoxia. The importance of epinephrine in connection with hypoglycemic reactions and the resulting blocking of vasomotor phenomena by ergotamine are recorded. Neither insulin nor the intermediate metabolism of carbohydrate is responsible for the reactions, but rather the nonutilization of dextrose supplied by the cerebral cells, because of anoxia. The second part of this chapter summarizes the production of hyperinsulinism by the ingestion of carbohydrate food, by fatigue, by hyperthermia, which generally has been overlooked, by faradic stimulation of the vagus nerve and by administration of pancreatropic hormones as described by Anselmino and Hoffmann (unconfirmed).

HEMOPNEUMOTHORAX

To the Editor:—A recent case of spontaneous hemopneumothorax appeared suddenly in a young man, a former serviceman, who had been previously well and in whom evidence of infection has not been found. Trauma was not a factor. What is the statistical incidence of such an entity compared to pneumothorax alone? Chest specialists here state that about 40 cases have been reported. Comment as to etiology is requested.

Jean P. Papps, M.D., Forest Hills, N. Y.

ANSWER.—Although hemopneumothorax from external trauma or incidental to the administration of therapeutic artificial pneumothorax is frequently observed, spontaneous hemopneumothorax is a rare occurrence. Nevertheless, a recent review cites 145 cases from the literature, and in spite of scores of papers on the subject, many cases remain unreported. More than two thirds of the reported cases have been complications of pulmonary tuberculosis. Malignant tumors of the lungs or of the chest wall and emphysematous blebs or cystic changes in the lungs account for many of the others (Korol, E.: Hemorrhagic Pleurisy of Tuberculous Origin and Hemopneumothorax, *Am. Rev. Tuberc.* **33**:185, 1936; Hartzell, H. C.: Spontaneous Hemopneumothorax, *Ann. Int. Med.* **17**:496, 1942; Bernstein, A., and others: Spontaneous Hemothorax, *Dis. of Chest* **12**: 394, 1946).

SENSITIVITY TO "DIAL"

To the Editor:—A patient has, on two occasions, taken hypnotic doses of 5-5-diallylbarbituric acid ("dial," Ciba) and within less than an hour has experienced an intense pruritus of the prepuce. Several days later a lesion typical of herpes developed. Phenobarbital and pentobarbital sodium caused no such reactions. The patient had a history of recurrent herpes preputialis several years ago but cannot recall whether he had been taking barbiturates. What connection, if any, could there be between the use of this barbiturate and the development of the herpes?

M.D., Canada.

ANSWER.—The question raises two possibilities. First, were the lesions actually herpes in the sense that the virus could have been recovered from them, or were they an eczematous eruption of a herpetiform appearance from which, if it had been searched for, the virus could not have been recovered? Assuming that the lesions actually were herpes simplex, of which herpes preputialis is a variant, apparently they could arise in a susceptible person from a variety of causes. It is believed by some that the virus lies dormant within the host and that any one of a number of factors may serve as a trigger mechanism to precipitate an attack. Such factors are physical ones as sunlight, cold or trauma, other infections and reactions to food or drugs. There are several reports in the literature of herpetic eruptions arising constantly after the ingestion of certain foods or the taking of various drugs

If the lesions were not a true herpes simplex but were herpetiform vesicular eruptions, the connection between them and the taking of the drugs is at least seemingly more obvious, inasmuch as such reactions are reported with greater frequency. As far as the patient's reacting to only one of the barbiturates, this is not surprising. One person may be sensitive to practically all members of the barbituric acid series, whereas another is sensitive only to one or two of the members. This is also true for the sulfonamide compounds and for the arsphenamine series and for local anesthetics of the procaine series. The explanation presumably is that in one instance the sensitivity is specifically directed toward a common factor as the malonylurea nucleus and in another case is directed to this ring plus a certain side chain or to the side chain alone.

BENZENE

To the Editor:—Please give information and references on the action of benzene (benzol) and lacquers on bone marrow. Have there been any cases of myelogenous leukemia reported in which the patient was exposed to lacquers, benzene or other chemicals? What is the current status of the treatment of leukemia with benzene?

Joseph D. Sacca, M.D., Flushing, N. Y.

ANSWER.—These toxic substances affect the bone marrow and blood in several ways depending on dosage, duration of exposure and individual susceptibility. Outstanding observations include anemia, leukopenia, thrombocytopenia and increased blood destruction (Erf, L. A., and Rhoads, C. P.: The Hematological Effects of Benzene [Benzol] Poisoning, *J. Indust. Hyg. & Toxicol.* **21**:421, 1939, and Goldwater, L. J.: Disturbances in the Blood Following Exposure to Benzol, *J. Lab. & Clin. Med.* **26**:957, 1941).

Cases have been described in which leukemia developed subsequent to exposure to chemicals (Erf and Rhoads). Leukemia is seldom treated with benzene today because of the associated dangers and because other more satisfactory methods are available.

BLASTOMYCOSIS

To the Editor:—Information is requested regarding: (1) recent advances in treatment of blastomycosis, particularly the lymphatic and pulmonary forms of the disease. Are any of the newer antibiotics of value? (2) Are sensitivity test materials (skin tests) available? What is their specificity and reliability?

Commander (MC), U. S. N.

ANSWER.—In systemic blastomycosis the lungs are involved in 95 per cent of the cases proved by autopsy, and it is probable in most instances that the primary lesion was in the lung. From this focus there may be a sudden generalization of the disease with subsequent lesions of the bones, joints, spleen, kidney, central nervous system and skin with subcutaneous abscesses.

In treatment of systemic types of blastomycosis it is believed that iodides not only fail to arrest the disease but may cause a rapid spread of the lesions. Martin and Smith (Blastomycosis, *Am. Rev. Tuberc.* **39**:275-299, [Jan.-June] 1939) recommend partially desensitizing the patient by injecting subreacting doses of blastomycotic vaccine prepared from the fungus and gradually increasing the dose starting with 0.1 cc., increasing the dose every two or three days until little or no reaction is elicited. Iodides can then be more safely administered and sometimes may cure the infection (cases 10 and 11 of Martin and Smith).

In spite of this advance in treatment the prognosis of systemic blastomycosis is extremely bad. None of the newer antibiotics have proved successful in the human being, although there is some encouraging experimental work with newer extracts of fungi, plants and bacteria which show a strong antibiologic activity against the pathogenic fungi The skin test with blastomycin, which is not an extract of the fungus but a vaccine, is of some value. Martin and Smith prepared their heat-killed vaccine by washing off the yeastlike growth on blood agar and diluting 1:1,000 by volume in sterile isotonic sodium chloride solution. Fifteen to twenty minutes after intracutaneous injection of this material a punctate erythema appears around the site of injection. The specific reaction is similar to a positive tuberculin reaction, appearing in twelve to twenty-four hours and reaching a maximum in two to four days. A state of anergy is seen in patients in the terminal stages of the disease. Unfortunately the reaction is not specific, as it is occasionally observed in patients with nonblastomycotic infection. (Dr. Donald S. Martin, assistant professor of bacteriology, Duke University School of Medicine, Durham, N. C., may be able to provide this vaccine.)

Martin also described a complement fixation test which appeared to be specific; however, a negative test does not exclude the diagnosis, for complement-fixing antibodies are absent from the blood in some cases.

MILIARY TUBERCULOSIS

To the Editor:—A white man aged 38 with inactive pulmonary tuberculosis received an injury to his left testicle on Feb. 17, 1947. Swelling and tenderness of the testicle occurred, accompanied with febrile reaction. He was treated symptomatically for a few days, but because of progress of the condition he was admitted to a general hospital. On March 6, 1947 an epididymotomy was performed for drainage of an abscess. The wound drained and closed alternately thereafter. Tubercle bacilli were later recovered from the wound. Chest films at this time revealed a miliary dissemination of tuberculosis in the lungs. Subsequently tuberculous meningitis ensued and the patient died Sept. 9, 1947 in spite of intensive streptomycin therapy extending over a period of five months.

The injury to his testicle in all probability lighted up a latent focus in the genitourinary tract, which sent tubercle bacilli into the blood stream, as shown by the generalized miliary distribution, and resulted in his death.

I have seen cases of miliary tuberculosis wherein autopsy proved the focus to be in the genitourinary tract, notably the prostate. Can instances be cited to support my position?

J. J. Hennessy, M.D., Hartford, Conn.

ANSWER.—There are abundant observations in the literature tending to support the idea that trauma may make latent tuberculosis active or may even determine the localization of tuberculosis if tubercle bacilli are in the blood stream. If a guinea pig is given a parenteral injection of tubercle bacilli and then receives an intramuscular injection of a suspension of silica, tuberculosis develops at the site of the injection of silica.

Surgical intervention of a tuberculous area, wherever it is localized in the body, may initiate miliary tuberculosis. The development of tuberculous epididymitis following trauma casts some doubt on the diagnosis of inactive tuberculosis. Extrapulmonary tuberculosis is most apt to develop in cases of chronic hematogenous pulmonary tuberculosis. This type of pulmonary tuberculosis causes few symptoms and practically no physical signs and is often considered to be inactive when actually it is active. This type of pulmonary tuberculosis is also associated with actual showers of tubercle bacilli in the blood stream and is the type in which miliary tuberculosis is most apt to develop.

NITRATE CONTENT AND METHEMOGLOBINEMIA OF WELL WATER

To the Editor:—I have had a case of methemoglobinemia in an infant 2 months of age as a result of the ingestion of well water with a high nitrate content, as described in the *Journal of Pediatrics* (November 1946). 1. How is the high nitrate content of well water caused? Is well water with a high nitrate content a common finding? If so, why is methemoglobinemia so rarely found? 2. Is a blood sample still satisfactory for methemoglobin estimation after twenty-four to forty-eight hours? 3. Methylene blue given intravenously is recommended in the treatment of more serious cases. How can methylene blue for injection be locally prepared and sterilized for intravenous injection in urgent cases? In what dosage is it administered orally? Who manufactures it for intravenous use? Is there any difference between methylene blue as used for staining purposes and that for oral use and for intravenous solution?

M.D., Canada

ANSWER.—1. High nitrate content of well water is probably caused by wells into which animal excreta, organic waste and surface water freely drain. Some wells may be satisfactory bacteriologically for drinking purposes, but this does not imply that such water cannot still be of a high content in nitrates; in filtering through soil the larger organic particles and bacteria are easily filtered out but the soluble nitrates remain. However, such wells are subject to bacteriologic contamination at any time. Many reports of similar cases of methemoglobinemia and well water with high nitrate content have been received since the recognition of the cause of cyanosis in some infants. The probable explanation for the few cases of methemoglobinemia caused by the ingestion of well water high in nitrate is that it is necessary for a relatively high amount of water to be ingested each day by the infant in order for enough nitrates to be converted to nitrite and thus cause methemoglobinemia. Another factor is that a certain amount of the methemoglobin is converted back to oxyhemoglobin each day, and if the production of methemoglobin is not in excess of that amount which is reconverted to oxyhemoglobin the clinical cyanosis will not appear. For this reason it is recommended that infants who are being fed artificial formulas in rural areas, especially if the condition of the well or the well water is suspected, should be given formulas which are relatively concentrated and do not necessitate the addition of a large amount of water. This means that whole cow's milk, if known to be bacteriologically safe, diluted with the necessary amount of water to make an acceptable formula should be used rather than evaporated or powdered milk in the preparation of formulas for infants in rural communities. As far as is known, there is no particular susceptibility of any infants to this condition. However, it must be noted that the signs and the symptoms which appear come primarily from the lowering of the amount of functional hemoglobin in the baby's blood stream, and for this reason if an infant is suffering from low hemoglobin in the first place and the additional loss of hemoglobin by conversion to methemoglobin is present, this infant is liable to show symptoms of anoxemia earlier than infants with a normal hemoglobin content.

2. Since methemoglobin is reoxidized to oxyhemoglobin on standing in contact with oxygen, it is necessary to make the methemoglobin estimation as quickly as possible after the blood is drawn. For this reason it is not profitable to depend on a sample of blood sent from a rural location to a proper laboratory for methemoglobin estimation. However, in an infant in which the condition is severe enough to be of concern, the blood grossly has a typical chocolate appearance as is observed in other forms of methemoglobinemia and can be seen when the blood is drawn into the syringe. Hence it is not necessary to depend on an estimation of methemoglobin before instituting therapy.

3. The use of methylene blue intravenously in such cases of methemoglobinemia effects a remarkable and instantaneous cure of the condition. The methylene blue, which is used in ampules as large as 50 to 100 cc. of a 1 per cent solution for the treatment of cyanide poisoning, is available in most centers. It is recognized that the use of this size ampule causes a great deal of waste of methylene blue solution, which is used in a much smaller dosage for the treatment of this condition. Methylene blue, if of a high chemical purity, can be prepared locally by making a 1 per cent solution and sterilizing by autoclaving and then administered in the dose of 1 to 2 mg. for each kilogram of body weight intravenously, but should not be recommended except in urgent cases. In less severe cases the methylene blue can be successfully administered orally in the dosage of 65 to 100 mg. of dye for each kilogram of body weight, although this is occasionally accompanied by vomiting and diarrhea. Methylene blue in 1 per cent solution in ampules from size 10 cc. to 100 cc. in boxes of six can be procured from William H. Rorer, Inc., 254 South Fourth, Philadelphia 6

There is no difference between the methylene blue used commonly for staining purposes and that used for oral administration or for preparation of intravenous solution, provided that it is of a high pharmaceutical grade.

ALUMINUM HYDROXIDE

To the Editor.—What is the information relative to early deleterious effects following prolonged aluminum hydroxide therapy for peptic ulcer?

M. J. Keren, M.D., Chicago.

ANSWER.—Aluminum hydroxide gel cannot be toxic because so much of it is being used every day by thousands of persons with ulcer, yet the literature is not full of reports of toxic reactions or late disasters.

Ehrmann (Ehrmann, R.: Drugs in the Treatment of Peptic Ulcer and Hypersecretion, *Am. J. Digest Dis.* **12**:154-156, 1945) stated that the substance apparently is not absorbed to any great extent, because there is no increase in the usual trace in the urine. However, he stated that there was slight absorption with deposition in the liver. He was of the opinion that aluminum should not be taken continuously by patients.

Beazell, Schmidt and Ivy (Beazell, J. M.; Schmidt, C. R.; and Ivy, W. C.: The Effect of Aluminum Hydroxide Cream on Absorption from the Gastrointestinal Tract, *ibid.* **5**:164-165, 1939) found that aluminum hydroxide given to dogs on a standard diet did not alter the fecal fat or content of nitrogen. When added to pancreatin in vitro it did not alter the tryptic or lipolytic activity. When it is put in the stomach it adsorbs a certain amount of pepsin. According to Grondahl and West (Grondahl, R. D., and West, E. S.: The Effect of Aluminum Hydroxide upon Food Utilization, *ibid.* **12**:197-199, 1945) administration of aluminum hydroxide increases the acidity of the urine.

Ivy and his associates pointed out the important fact that aluminum hydroxide gel withdraws phosphorus from the body; hence, to avoid this depletion it is well to give a phosphate gel which contains phosphorus.

In practical use the main objection to giving the aluminum gels is that they often produce constipation. According to Lichstein, Simpkins and Bernstein (Lichstein, J.; Simpkins, S., and Bernstein, M.: Aluminum Phosphate Gel in the Treatment of Peptic Ulcer, *ibid.* **12**:65-67, 1945) the aluminum phosphate gel has less constipating effect than the ordinary aluminum gel.

Hoffman and Dyniewicz (Hoffman, W. S., and Dyniewicz, H. A.: The Effect of Alumina Gel upon the Absorption of Vitamin A from the Intestinal Tract, *Gastroenterol* **5**:512-522, 1945) found that aluminum gel has only a slightly depressant effect on the absorption of vitamin A. No depression of the tolerance curve for vitamin A was noted in 6 cases in which aluminum phosphate gel was used instead of aluminum gel. In 33 patients with peptic ulcer who had been on aluminum gel for two or more weeks, the plasma vitamin A and plasma carotenoid concentrations were apparently normal. There was a slight lowering of the absorption of amino acids, ascorbic acid and dextrose. However, from a nutritional point of view therapeutic doses of aluminum phosphate gel had no demonstrative effect on the absorption of the nutrient substances studied.

For an ordinary ulcer cure of a month or two there does not seem to be any reason for fearing the use of aluminum gel, but it might be wise not to keep taking it day in and day out for years.

ENLARGED HEART

To the Editor:—Are there known cases of enlarged hearts, due to myocardial toxicity from distant infection or from rheumatic fever, that have after a number of years returned to normal size? I do not refer to reversibility in acute conditions. Has rheumatic fever ever been treated from the allergic approach, i. e., antihistamine substances or adrenaline-like drugs?

M.D., Philadelphia.

ANSWER.—Many instances occur in which a heart enlarged as the result of rheumatic fever has been found years later to be normal in size. Some observers believe this is due to failure of the heart to increase further in size, as normal growth occurs (especially of the thoracic cage), rather than to an actual decrease in the size of the heart. The absence of recurrent rheumatic fever would seem to be the most pertinent means whereby this beneficial situation develops. A well substantiated and striking decrease in heart size has been demonstrated following the treatment of anemia of hookworm infestation. Change in the heart size on recovery from diphtheritic myocarditis could be cited as an instance of a similar change following the effect of a toxin on the heart muscle. There have been numerous attempts to treat rheumatic fever from the usual allergic approach with so-called blocking substances. There are no published reports indicating that such therapy is beneficial in rheumatic fever.

SYPHILIS IN PREGNANCY

To the Editor:-A young white woman, aged 26 ,was found to have a positive serologic response to the Wassermann test on a premarital examination in July 1947. She gave a history of a generalized papular rash a year and a half previously. On July 18, 1947 she had a Kahn determination of 444 and a Kolmer of 512 units. She was given some treatments, amount unknown, in a clinic in San Francisco and was then referred to a clinic closer to her home, where further treatment was carried out. Tests at this second clinic on August 18 revealed that she had a 4 plus Kahn and a 64 unit Kolmer. Between August 20 and 29 she was given 3,000,000 units of penicillin in oil and wax in divided doses. five injections of oxophenarsine hydrochloride "mapharsen" 0.06 Gm., and three injections of a bismuth preparation. Her titers since that date have been as follows: November 26, 64 units; December 31, 8 units, and Jan. 16, 1948, Kahn 4 plus, Kolmer 4 plus, titer unknown. The spinal fluid is normal. This young woman has married and is now three months pregnant. Her husband is negative. She is now a patient of mine and I wish to know whether she should have further treatment or if it is believed that her serologic titer will continue to fall. A check on the titer is to be made each month. This patient has no symptoms other than a positive serologic response at the present time.

M.D., California

ANSWER.—In view of the fact that this patient received something less than the probably desirable dose of penicillin for early latent syphilis (which is in the neighborhood of 5,000,000 units) and that she is now pregnant, retreatment with penicillin is desirable. There is some evidence that in pregnant syphilitic women penicillin in aqueous solution administered every two to three hours around the clock, is more effective than penicillin in oil and beeswax. It is suggested that the patient now be hospitalized and retreated with crystalline penicillin G, 50,000 units every two hours day and night for eight days to a total of 4,000,000 units. Following this, monthly quantitatively titered serologic tests for syphilis should be performed as after the original treatment.

"DICUMAROL" AND SEDIMENTATION RATE

To the Editor:—To what extent is the value of the blood sedimentation rate for determining progress in a case of myocardial infarction altered by "dicumarol" therapy?

G. B. Sanders, M.D., Louisville, Ky.

ANSWER.—In experimental myocardial infarction in dogs "dicumarol" is said to have had no effect on the sedimentation rate *(J. Lab & Clin. Med. 32: 1417, 1947)*. Heparin in vitro causes a striking but little understood inhibition of the rate of sedimentation of red cells. It is doubtful that the sedimentation rate would be altered appreciably by blood concentrations encountered in patients treated with heparin For practical purposes, the influence that anticoagulants may have on the rate of sedimentation of red cells may be disregarded. Finally, it may be added that the value of the sedimentation rate in gaging the progress of healing of a myocardial scar is doubtful. The test is nonspecific and is easily influenced by a variety of factors liable to interfere with convalescence from myocardial infarction.

OZONE TREATMENT

To the Editor:--What are the values and dangers of the "ozone treatment" for multiple sclerosis, arthritis, sinusitis, the common cold and influenza? Certain practitioners in Tucson are using radar rays in treating some of these conditions. Please supply information about ozone or radar treatments.

Elizabeth H. Laidlow, M.D., Tucson Ariz.

ANSWER.--Several pieces of apparatus for producing ozone have been placed on sale in this country during recent years These have been advertised extravagantly as effective in curing various diseases. On investigation, these machines have shown no therapeutic value and some have been condemned as harmful. The Federal Trade Comission has successfully taken court action to halt the unjustified claims of at least one manufacturer of this type of machine. In general, claims for the curative value of these machines have been supported only by testimonials.

In order for ozone to be effective even slightly as a bactericidal agent, it must be present in such high concentrations as are distinctly harmful to the mucous membranes of the nose, throat and lungs of man. If present in concentrations which can be breathed over reasonable periods without such irritation, no protective action against air-borne bacteria can be demonstrated, and certainly no therapeutic value against bacteria could possibly be expected. There is not one shred of scientific evidence to suggest that any ozone machine can help persons with the diseases mentioned.

MULTIPLE BIRTHS

To the Editor:—Recently a Syracuse mother, 40 years of age, was delivered of triplets after having been delivered of triplets in the pregnancy directly preceding this one. All six of the children are alive and healthy. As this is apparently an extremely rare occurrence, the entire community has become intensely interested. There have been varying reports as to whether there have been previously recorded two successive sets of triplets all of whom are living. I would greatly appreciate any information on this point and especially a reference to a a description of a previous similar occurrence.

M.D., New York.

ANSWER.--There are three well established records of the birth of triplets twice to the same woman (Hornstein, M.: Triplets Twice in One Year (Same Mother), *J.A.M.A.* 79:224, [Jan. 26] 1918; Uthmoller, A.: Two Sets of Triplets, *Zentralbl. f. d.ges. Gynaek. u. Geburtsh* 46:859-861 [May 17] 1922, and Breipohl, W.: Second Triple Pregnancy; Case, ibid. 61:931-938 [April 17] 1937. Breipohl refers to the book by E. Bumm, "Grundriss zum Studium der Geburtshulfe in Achtundzwanzig Vorlesungen," (Wiesbaden J. F. Bergman, 1902), in which von Boer and Valenta have reported many multiple births in one mother; for example. six sets of triplets, two sets of quadruplets. There are, of course, many reports of great numbers of children born to one mother in quantities of twins and triplets which are not well authenticated. A great many such instances are reported in the book by G. M. Gould and W. L. Pyle called "Anomalies and Curiosities of Medicine " (Philadelphia, W. B. Saunders, 1897).

MUSCULAR CRAMPS AFTER "MERCUPURIN"

To the Editor:—The note by Dr. A.H. Ulm, New York, in Queries and Minor Notes, THE JOURNAL, February 7, p. 434,on the occurrence of muscular cramps and paresthesias following the use of "mercupurin" is interesting. I have had the opportunity to observe several similar incidents. These symptoms can be promptly relieved by the administration of calcium gluconate and / or isotonic sodium chloride solution intravenously. Ten cubic centimeters of a 10 per cent solution of calcium gluconate will provide immediate relief. If this is not available, salt by mouth will give a similar but slower result. It is my impression that these symptoms are due to changes in salt balance secondary to diuresis. Most of these patients have been on low salt diets, and this makes them more susceptible. It hardly seems justifiable to blame the mercury for the reaction.

Perry S. MacNeal, M.D., Philadelphia.
